

Quantifying and predicting the evolution of RNA viruses

Richard Neher
Max Planck Institute for Developmental Biology

Slowly evolving populations

Slowly evolving populations

Slowly evolving populations

evolutionary processes ↔ statistics of trees ↔ patterns of genetic diversity

→ time resolved data allows direct observation

Slowly evolving populations

evolutionary processes ↔ statistics of trees ↔ patterns of genetic diversity

→ time resolved data allows direct observation

Rapidly evolving populations

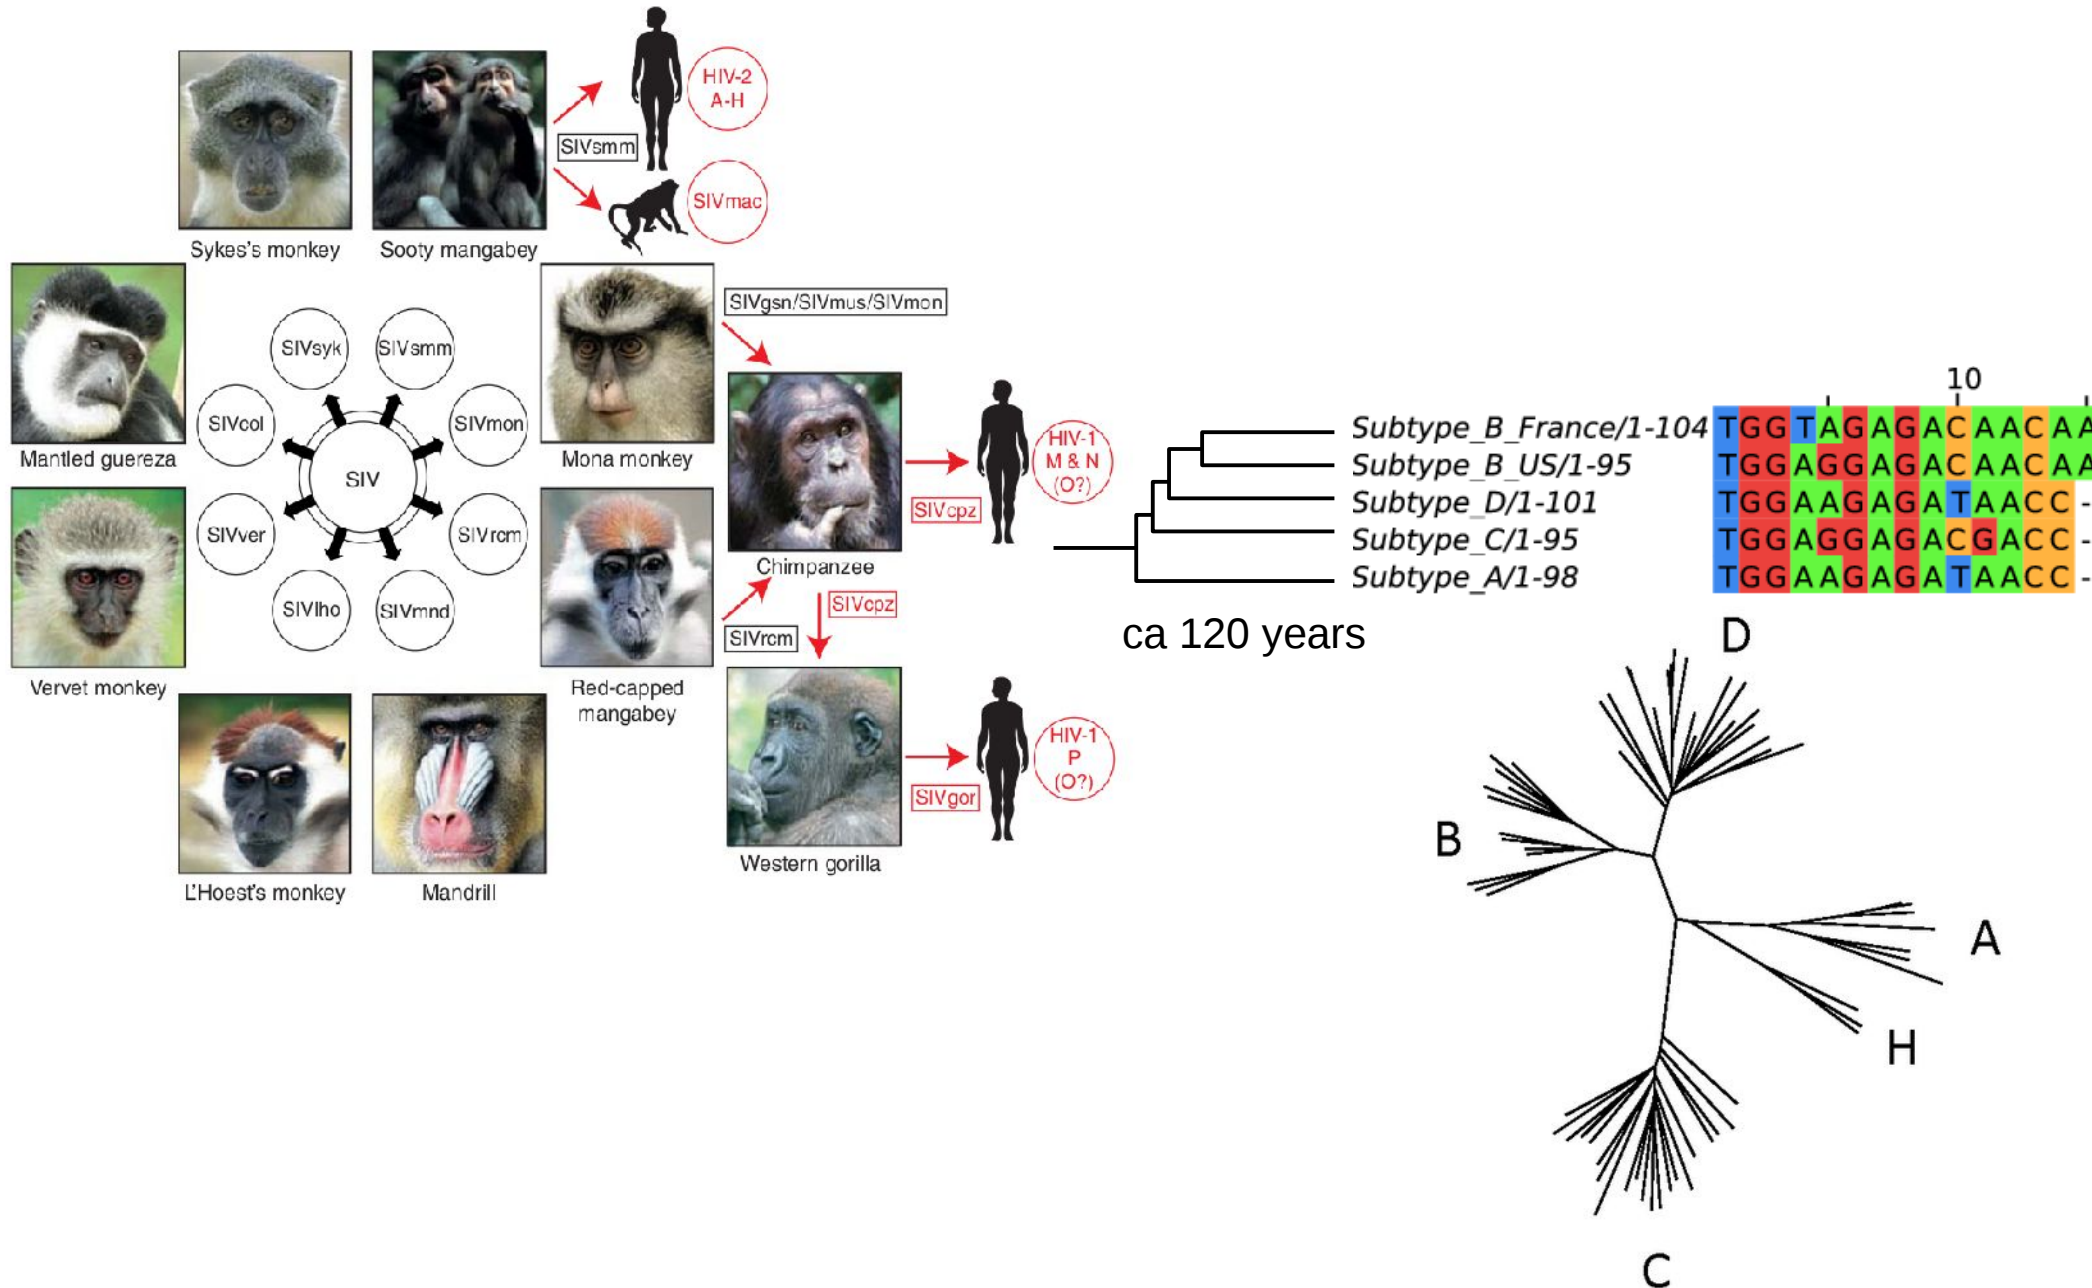

Influenza H3N2: 2003-2005

RNA viruses evolve 10^6 times than eukaryotes

- direct observation of the dynamics
- good understanding of the phenotype
- HIV and influenza viruses

History of HIV

HIV-1 infection and immune selection

virus-immune system coevolution

- rapid evolution facilitates chronic infection
- paradigmatic example of host-parasite co-evolution
- can be studied in exquisite detail

The dynamics of mutations

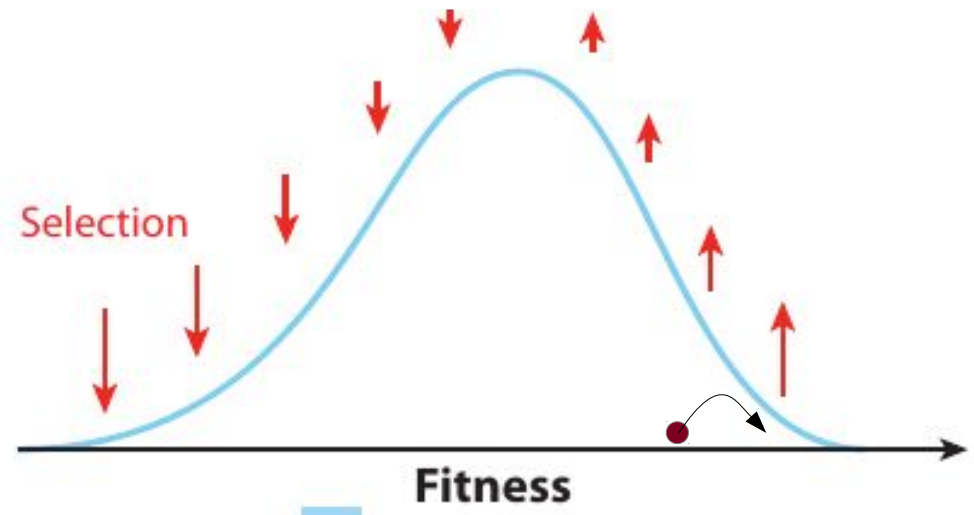

What is an appropriate model?

Why does it look like Bolthausen-Sznitman?

A large fraction of genetic variation is under selection

- there is a broad fitness distribution
- successful parents have successful offspring

Coalescence with selection

Neutral coalescence

Coalescence with selection

RN and Hallatschek, PNAS, 2013

Coalescence with selection

Branching process approximation:

$$P(n_i | \chi_i, \tau)$$

Coalescence with selection

Does a sample (blue dots) have a common ancestor tau generations ago?

$$Q_b = \left\langle \sum_i \left(\frac{n_i}{\sum_j n_j} \right)^b \right\rangle = \begin{cases} \mathcal{O}(1/N) & \tau < T_c \\ \frac{\tau - T_c}{T_c(b-1)} & \tau > T_c \end{cases}$$

All other merger rates also suggest a Bolthausen-Sznitman coalescent

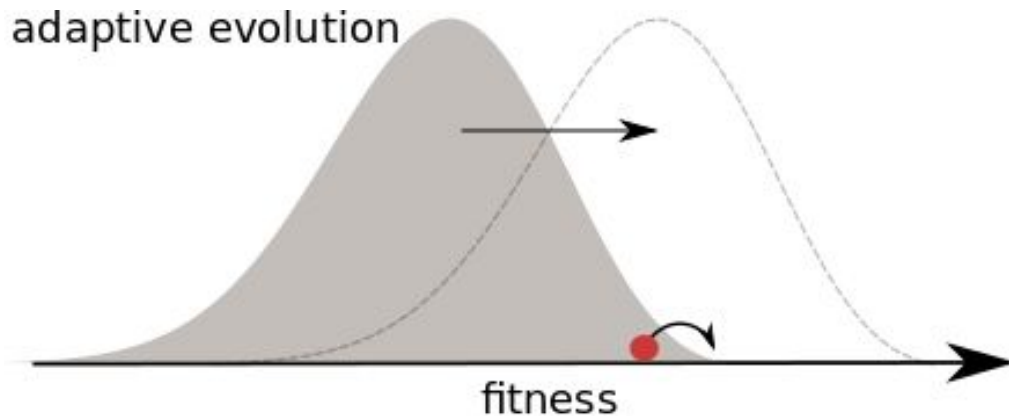

Allele frequency spectra

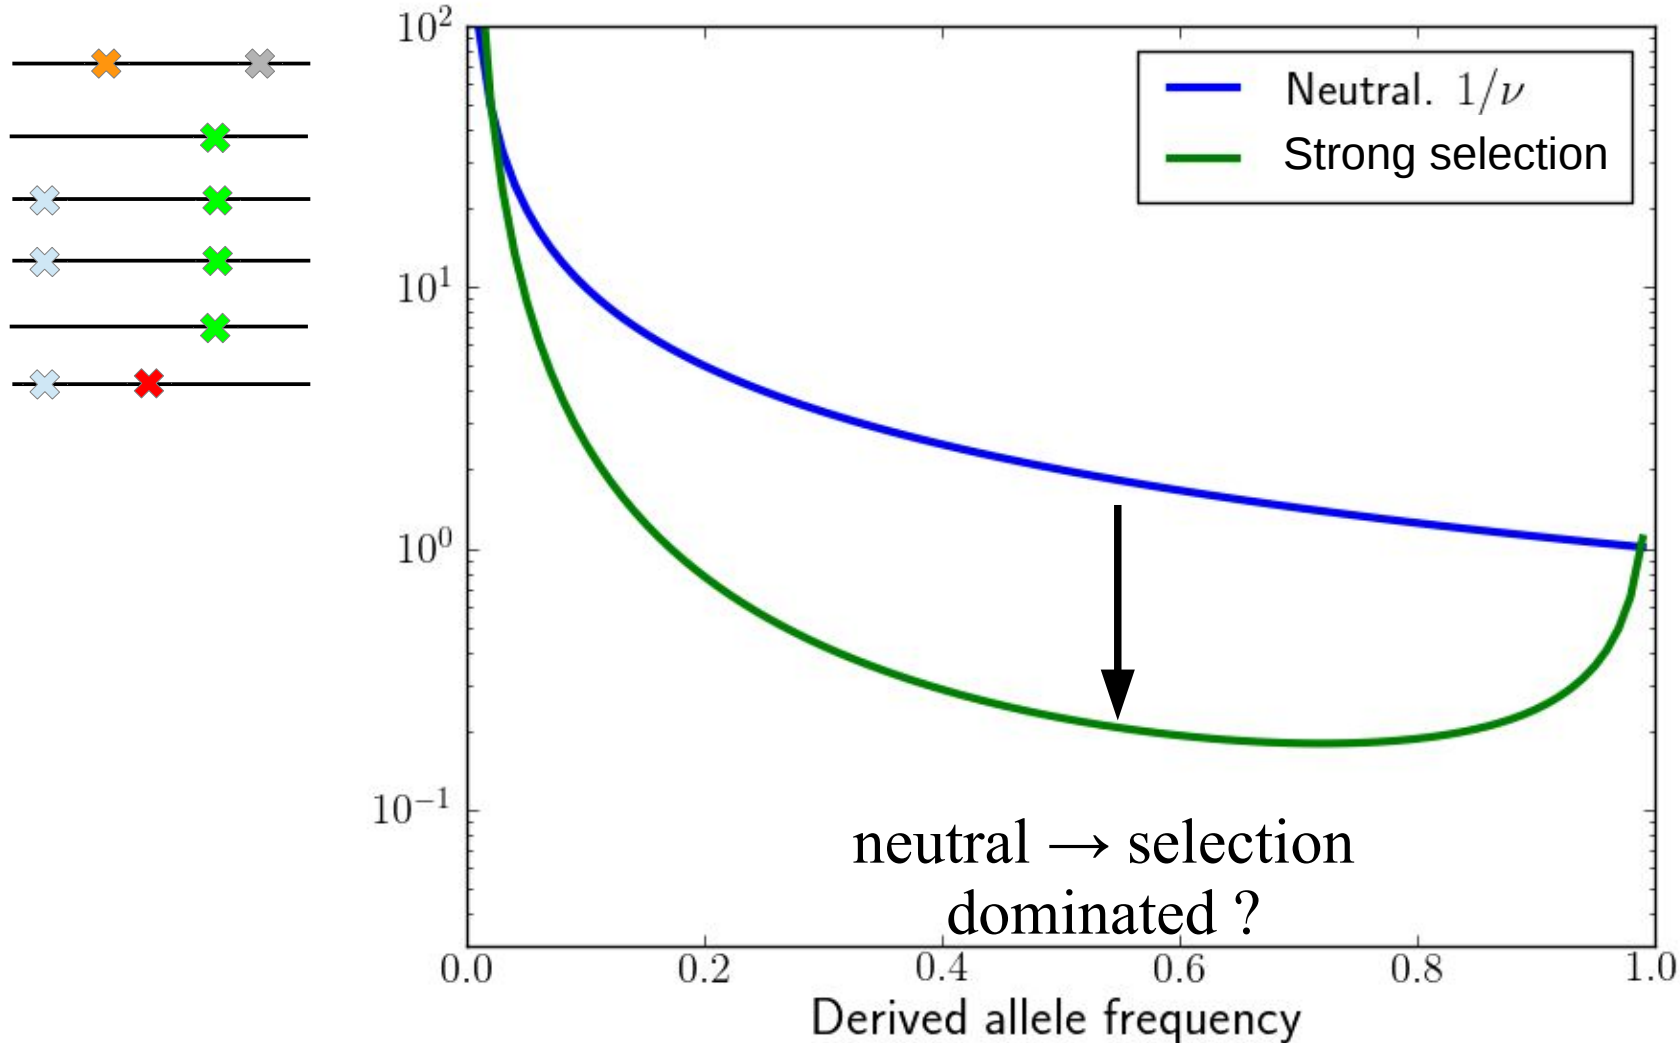

Genetic diversity in adapting populations

Time scale of coalescence: $T_c \sim \frac{\sqrt{\log N}}{\sigma}$

Universal: many selected mutations \rightarrow same tree statistics

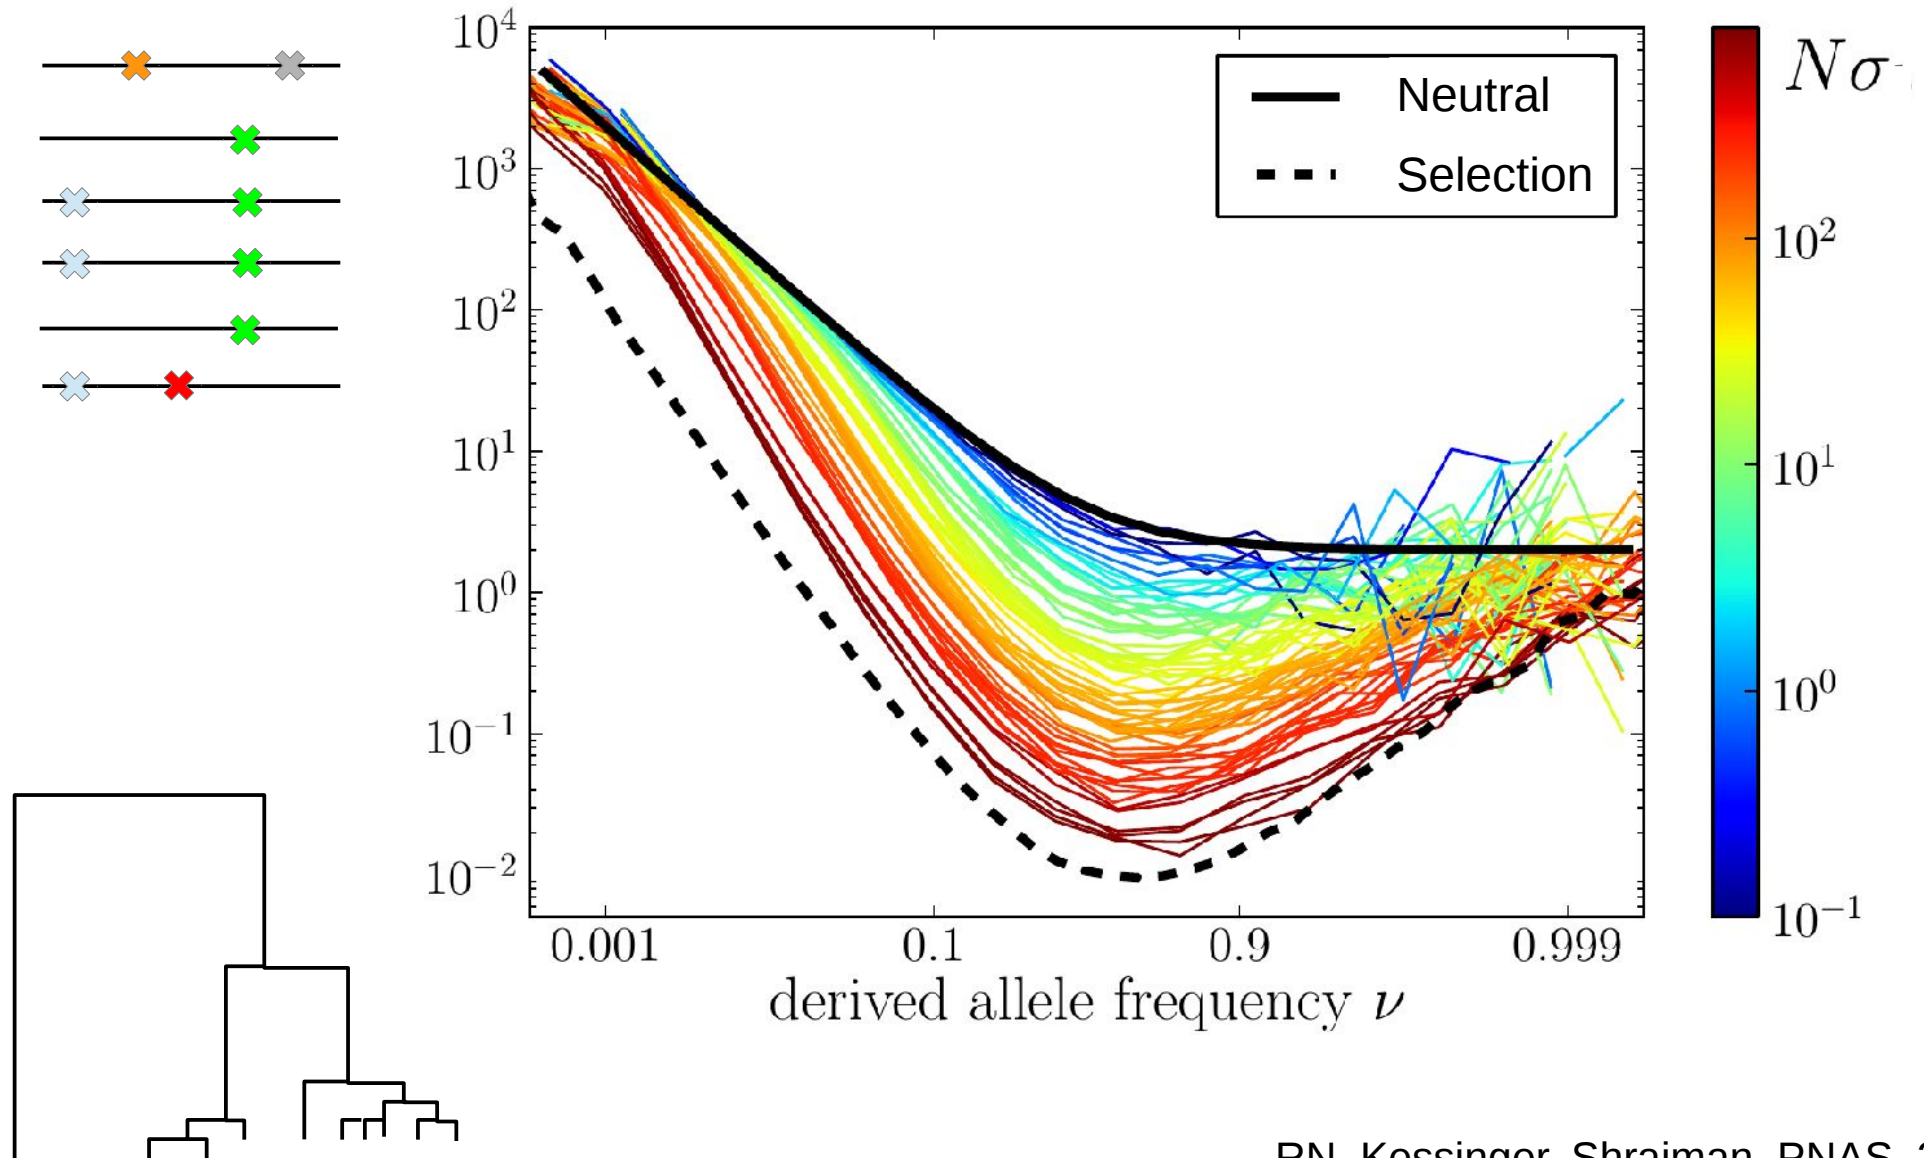

Continuous cross-over from neutral to strongly selected

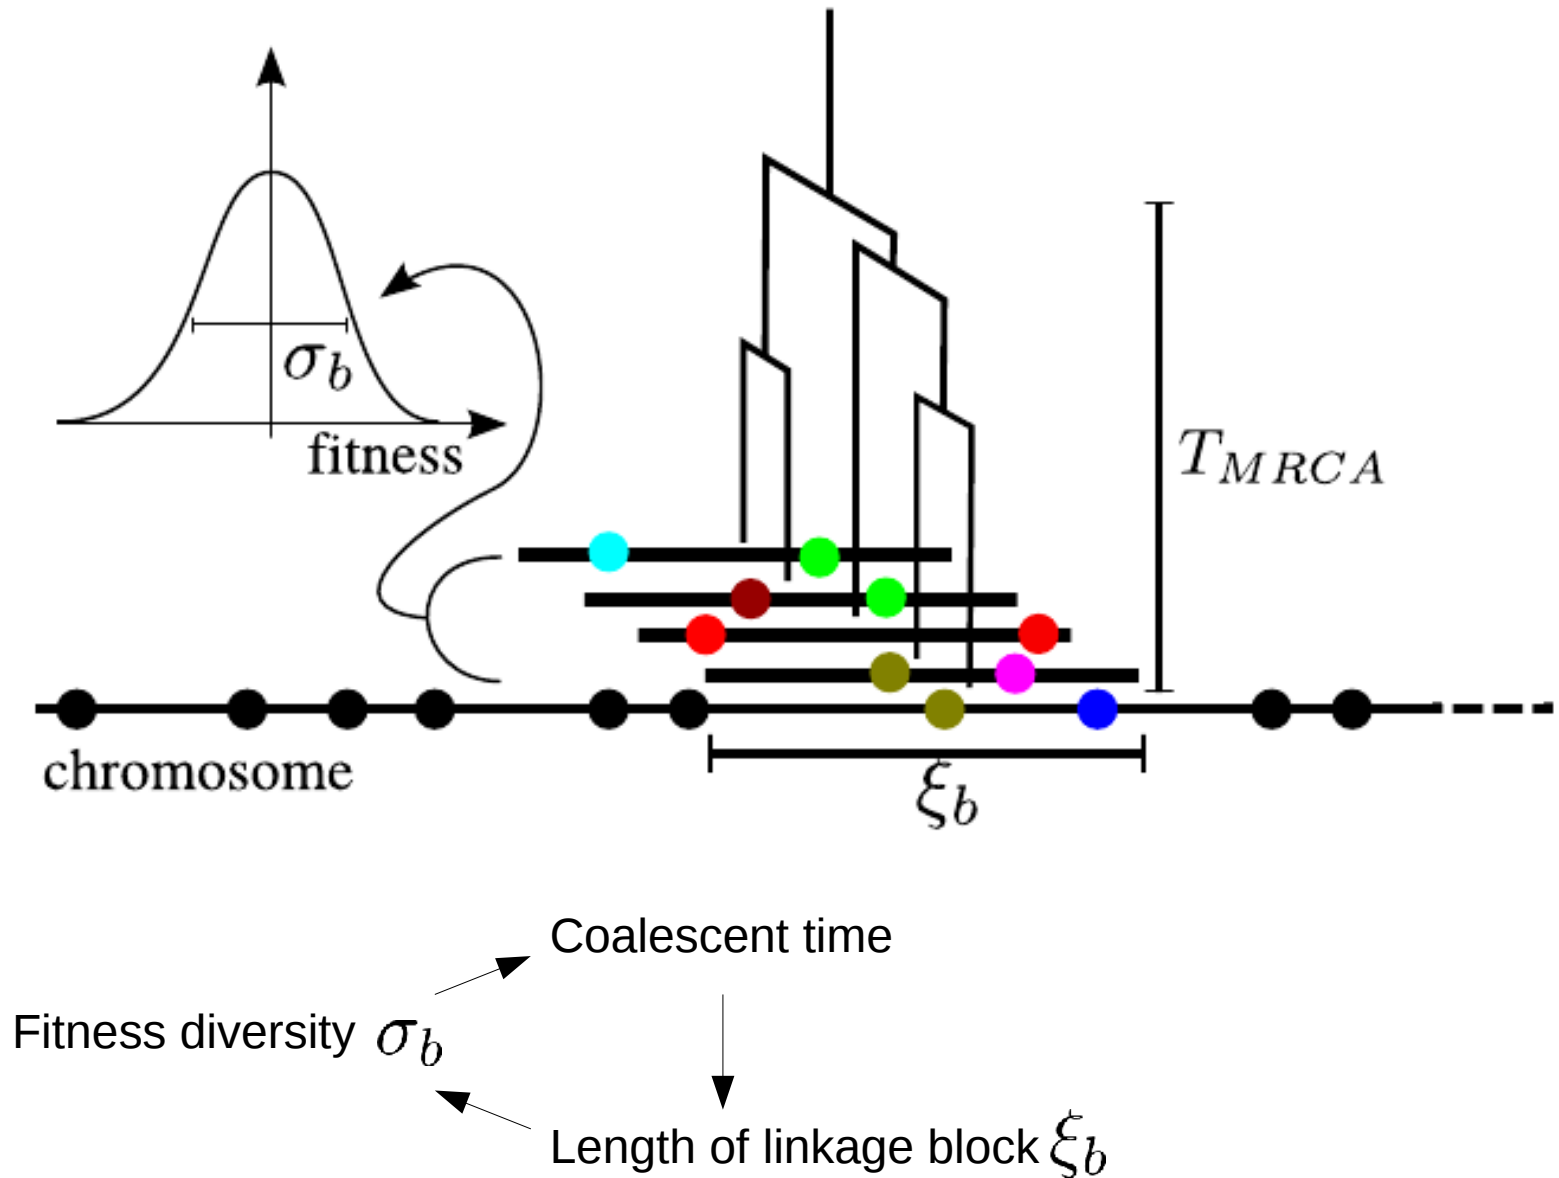

Continuous cross-over from neutral to strongly selected

Continuous cross-over from neutral to strongly selected

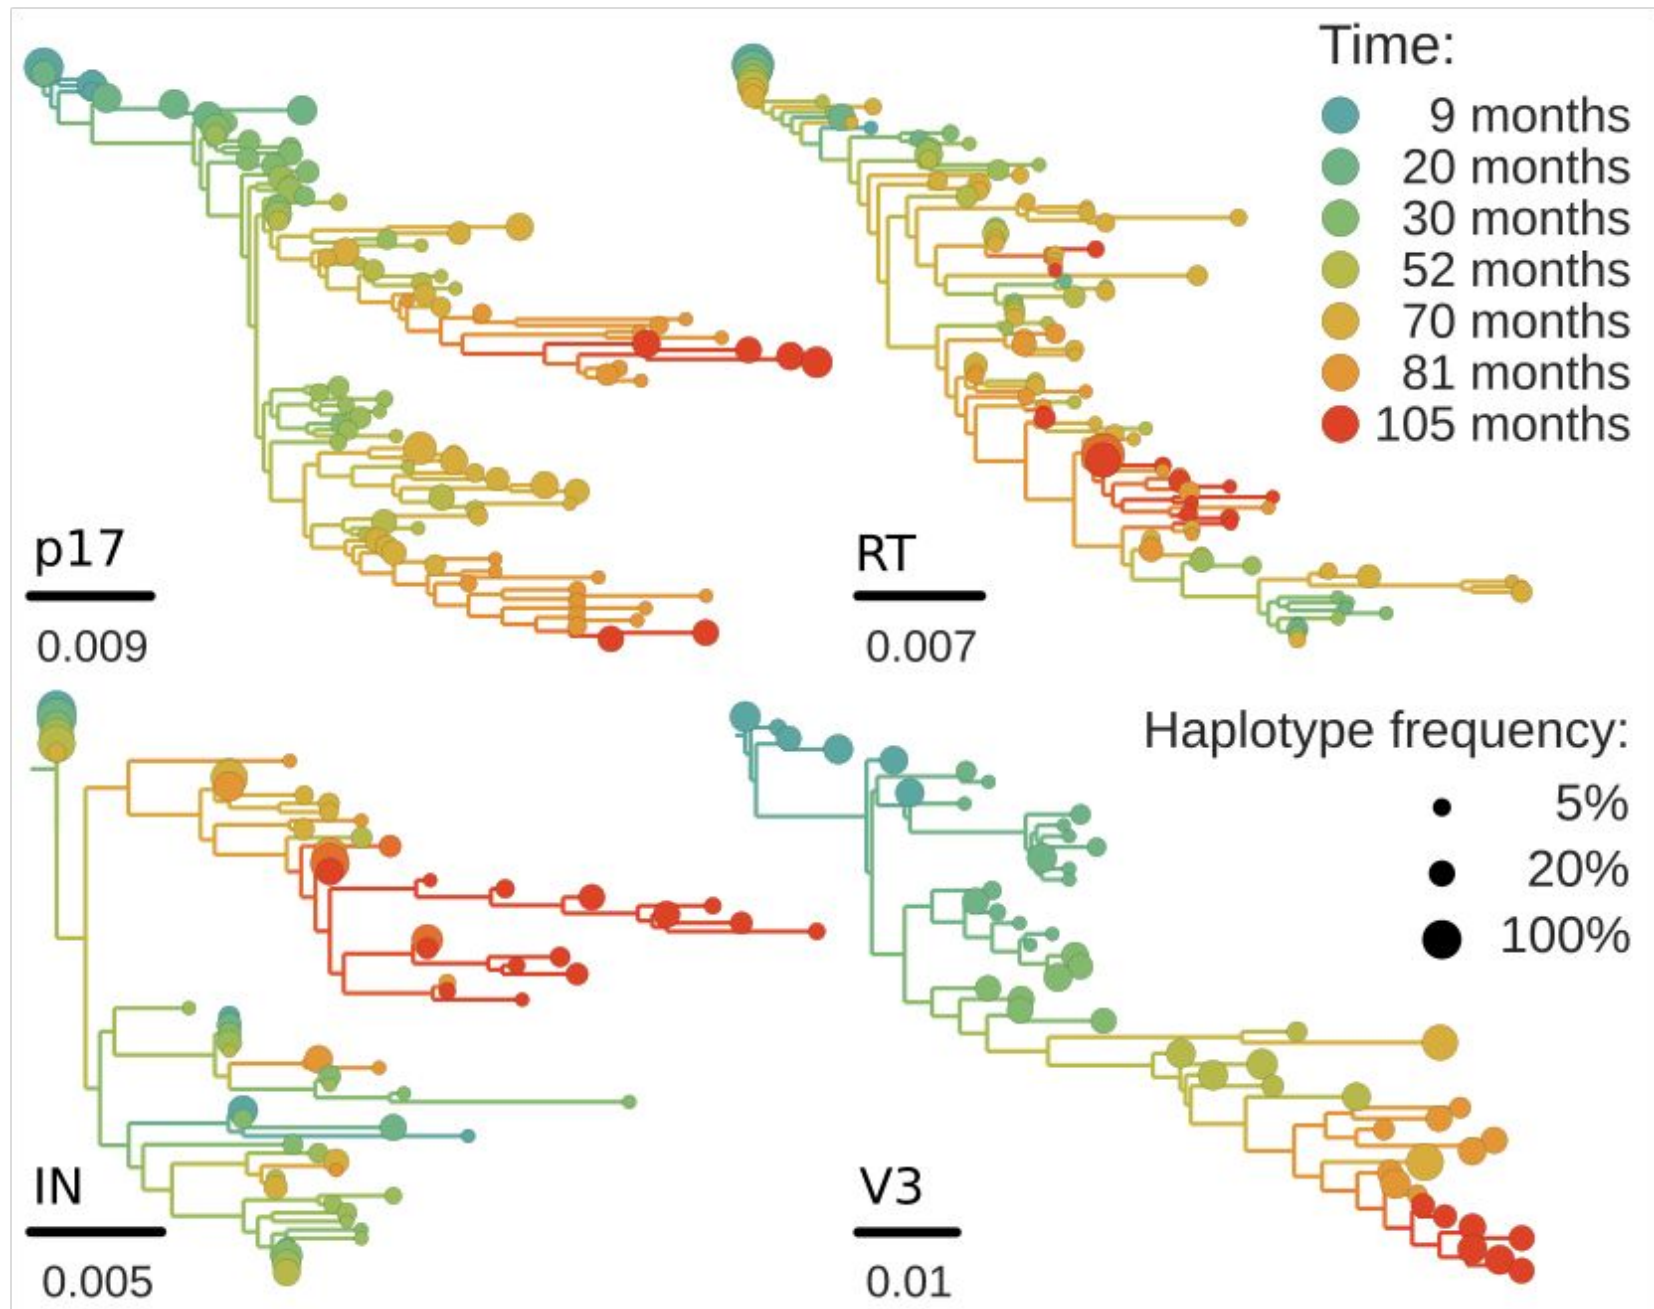

Extension to recombining populations

Site frequency spectra

Phylogenetic trees in different regions

Movie

Recombination facilitates adaptation

Constrasting behavior:

- Non-synonymous diversity is low, region specific rate of evolution
- Synonymous diversity keeps increasing, rate is identical across regions
- Synonymous diversity is inversely related to non-synonymous divergence

Recombination facilitates adaptation

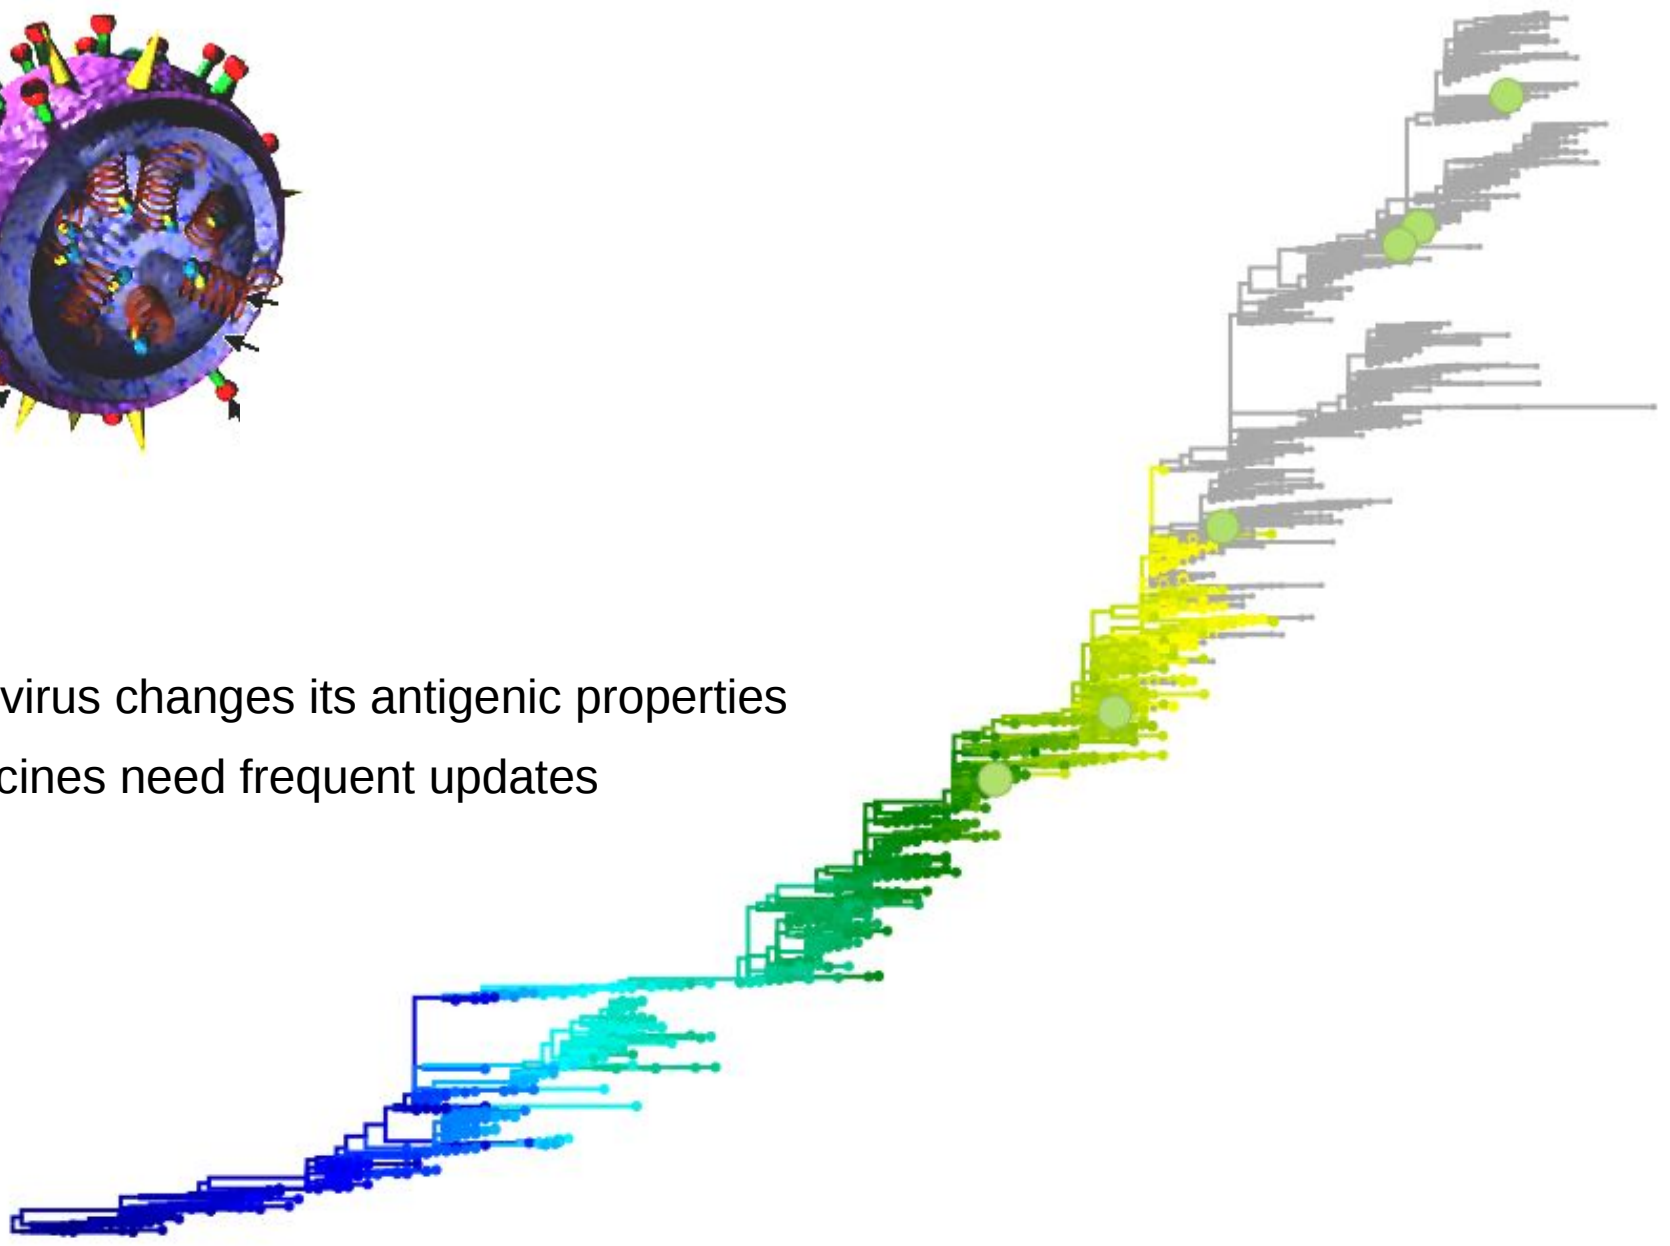

Constrasting behavior:

- Non-synonymous diversity is low, region specific rate of evolution
- Synonymous diversity keeps increasing, rate is identical across regions
- Synonymous diversity is inversely related to non-synonymous divergence

Predicting Influenza evolution?

- the virus changes its antigenic properties
- vaccines need frequent updates

Predicting Influenza evolution?

Best pick for new vaccine!

Given the branching pattern, can we

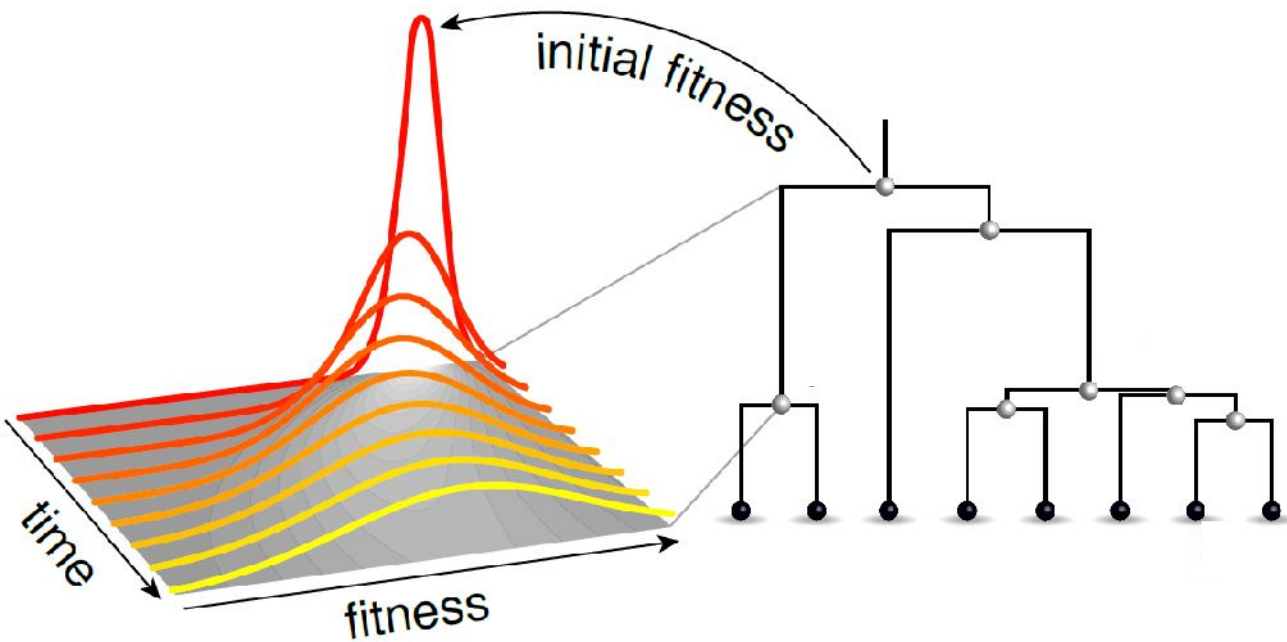

- predict fitness?
- pick the most likely progenitor of the future?

Fitness can be inferred from trees

$$P(\mathbf{x}|T) = \frac{1}{Z(T)} p_0(x_0) \prod_{i=0}^{n_{int}} g(x_{i_1}, t_{i_1} | x_i, t_i) g(x_{i_2}, t_{i_2} | x_i, t_i)$$

Fitness can be inferred from trees

$$P(\mathbf{x}|T) = \frac{1}{Z(T)} p_0(x_0) \prod_{i=0}^{n_{int}} g(x_{i_1}, t_{i_1} | x_i, t_i) g(x_{i_2}, t_{i_2} | x_i, t_i)$$

$$\partial_t g(x, t' | y, t) = [y - 2\phi_\omega(y, t)] g(x, t' | y, t) - \sigma^2 \partial_y g(x, t' | y, t) + D \partial_y^2 g(x, t' | y, t)$$

Fitness can be inferred from trees

$$P(\mathbf{x}|T) = \frac{1}{Z(T)} p_0(x_0) \prod_{i=0}^{n_{int}} g(x_{i_1}, t_{i_1} | x_i, t_i) g(x_{i_2}, t_{i_2} | x_i, t_i)$$

$$\partial_t g(x, t' | y, t) = [y - 2\phi_\omega(y, t)] g(x, t' | y, t) - \sigma^2 \partial_y g(x, t' | y, t) + D \partial_y^2 g(x, t' | y, t)$$

High fitness corresponds to local bursts

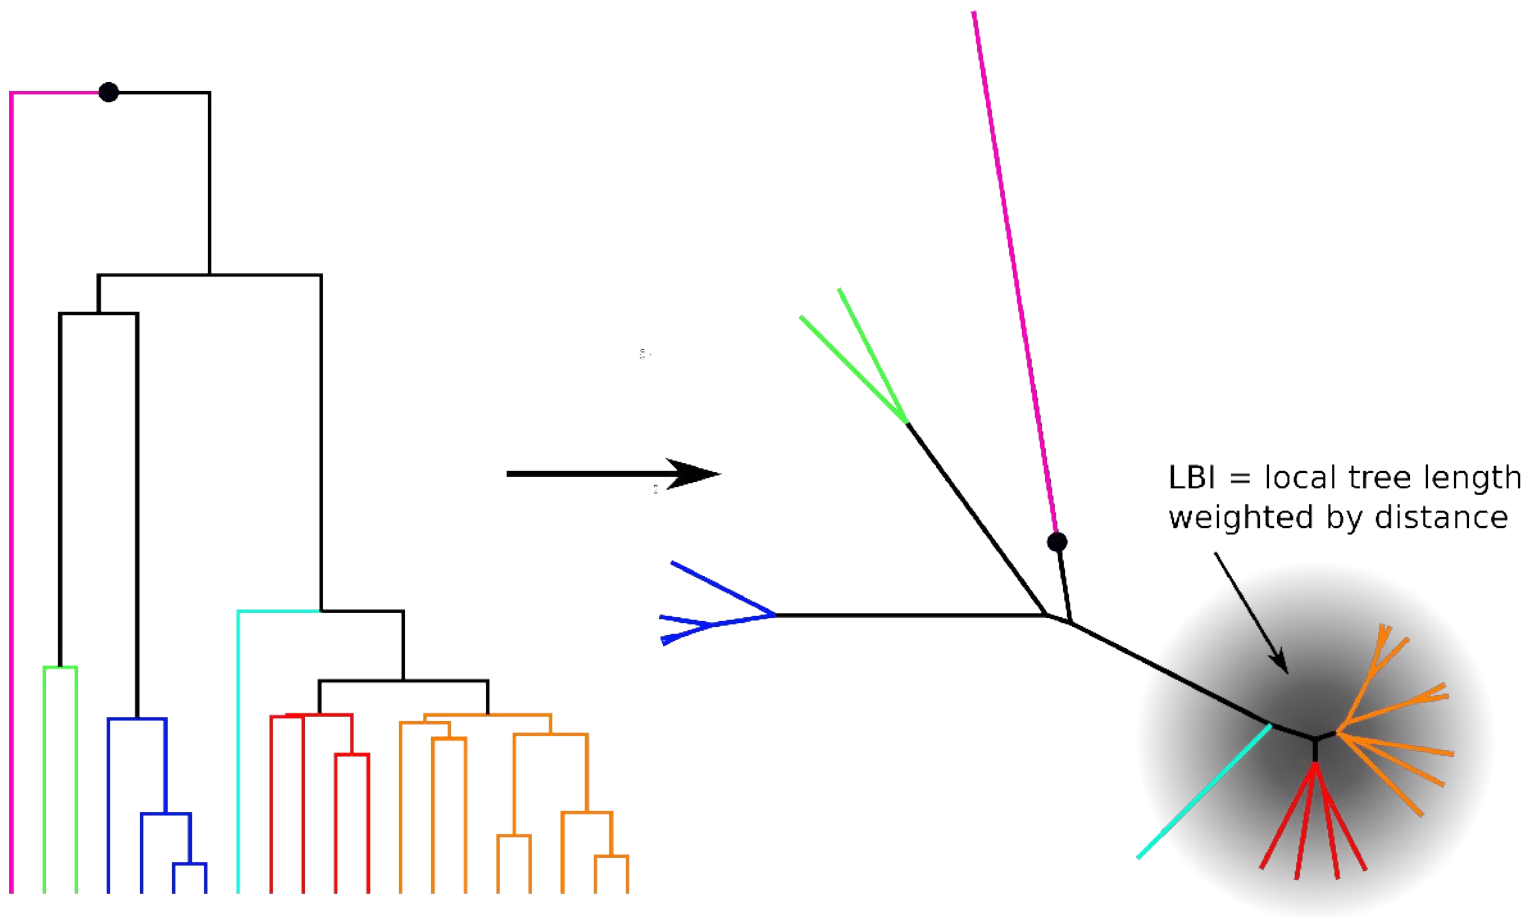

At short times: $\int dx g(x, t|y, t') \sim e^{y(t-t')}$

→ the product of propagators and prior: $\sim e^{yT - y^2/2}$

High fitness corresponds to local bursts

Past evolution of influenza A/H3N2 is predictable

- requires only tree as input: generally applicable
 - emerging diseases
 - cancer cell populations

Summary

- 
- HIV-1 evolution can be followed in exquisite detail
 - RNA virus evolution is driven by ubiquitous selection
 - Genealogies share properties with the Bolthausen-Sznitman coalescent
 - Fitness can be inferred from trees
 - Influenza evolution is predictable
 - Browser-based tools to integrate information
