Abstract

The objective of this work is to prove in a first step the existence and the uniqueness of a solution of the following multivalued deterministic differential equation:

\[
\begin{aligned}
&dx(t) + \partial^- \varphi(x(t))(dt) \ni dm(t), \\
x(0) = x_0,
\end{aligned}
\]

where \( m : \mathbb{R}_+ \to \mathbb{R}^d \) is a continuous function and \( \partial^- \varphi \) is the Fréchet subdifferential of a \((\rho, \gamma)\)-semiconvex function \( \varphi \); the domain of \( \varphi \) can be non-convex, but some regularities of the boundary are required.

The continuity of the map \( m \mapsto x : C([0, T]; \mathbb{R}^d) \to C([0, T]; \mathbb{R}^d) \) associating to the input function \( m \) the solution \( x \) of the above equation, as well as tightness criteria allows to pass from the above deterministic case to the following stochastic variational inequality driven by a multi-dimensional Brownian motion:

\[
\begin{aligned}
&X_t + K_t = \xi + \int_0^t F(s, X_s)ds + \int_0^t G(s, X_s)dB_s, \\
&dK_t(\omega) \in \partial^- \varphi(X_t(\omega))(dt).
\end{aligned}
\]

1. Introduction

Given a multi-dimensional Brownian motion $B = (B_t)$ and a proper $(\rho, \gamma)$-semiconvex function $\varphi$ (for the definition the reader is referred to Definition 11 from the next section) defined over a possibly non-convex domain $\text{Dom}(\varphi)$ and a random variable $\xi$ independent of $B$, which takes its values in the closure of $\text{Dom}(\varphi)$, we are interested in the following multi-valued stochastic differential equations (also called stochastic variational inequality) driven by the Fréchet subdifferential operator $\partial^-(\varphi)$:

$$
\begin{align*}
X_t + K_t &= \xi + \int_0^t F(s, X_s)ds + \int_0^t G(s, X_s)dB_s, \quad t \geq 0, \\
dK_t(\omega) &\in \partial^-(\varphi)(X_t(\omega))(dt).
\end{align*}
$$

However, in order to study the above system, we shall first solve the following deterministic counterpart of the above equation. Given a continuous function $m : \mathbb{R}_+ \to \mathbb{R}^d$ and an initial value $x_0 \in \text{Dom}(\varphi)$ we look for a pair of continuous functions $(x, k) : \mathbb{R}_+ \to \mathbb{R}^{2d}$ such that

$$
\begin{align*}
x(t) + k(t) &= x_0 + \int_0^t f(s, x(s))ds + m(t), \quad t \geq 0, \\
dk(t) &\in \partial^-(\varphi)(x(t))(dt)
\end{align*}
$$

(for the notation $dk(t) \in \partial^-(\varphi)(x(t))(dt)$ see Definition 11 and Remark 15).

With the particular choice of $f \equiv 0$ and $\varphi$ as convexity indicator function of a closed domain $E \subset \mathbb{R}^d$,

$$
\varphi(x) = I_E(x) := \begin{cases} 
0, & \text{if } x \in E, \\
+\infty, & \text{if } x \notin E,
\end{cases}
$$

equation (2) turns out to be just the Skorohod problem, i.e., a reflection problem, associated to the data $x_0$, $m$ and $E$. For this reason we will refer to equation (1) as Skorohod equation.

The existence of solutions for both the Skorohod equation (2) and for the stochastic equation (1), has been well studied by different authors for the case, where $\varphi$ is a convex function. In this case $\partial^-(\varphi)$ becomes a maximal monotone operator and the domain $\text{Dom}(\varphi)$ in which the solution is kept is convex. By replacing $\partial^-(\varphi)$ by a general maximal monotone operator $A$, E. Cépa

Please cite this article in press as: R. Buckdahn et al., Stochastic variational inequalities on non-convex domains, J. Differential Equations (2015), http://dx.doi.org/10.1016/j.jde.2015.08.023
generalized in [14] the above equation in the finite dimensional case, while A. Rășcanu [32]
investigated the infinite dimensional case.

Deterministic variational inequalities with regular inputs, i.e., deterministic equations of
type (2), with convex ϕ and m = 0 have been well studied and the corresponding results have
by now become classical. As concerns the non-convex framework, the reader is referred to
A. Marino, M. Tosques [26], M. Degioanni, A. Marino, M. Tosques [19], A. Marino, C. Sac-
con, M. Tosques [25] or R. Rossi, G. Savaré [36,37]. They used the concept of ϕ-convexity
(see, e.g., [26, Definition 4.1]) and they provide the existence, uniqueness and continuous de-
dependence on the initial data of the solutions for the evolution equation of type (2) in the case
m = 0, f = 0 (or f (t, x(t)) = f(t) in [37]). We specify that our notion of (ρ, γ)-semiconvex
function corresponds to the particular case of a ϕ-convex function of order r = 1 with
ϕ (x, y, φ (x), φ (y), α ) := ρ + γ |α|. This particular form was required by the presence of the
singular input dm/dt.

Related to our problem is the research on non-convex differential inclusions, see, e.g., F. Pa-
In [15] it is proved the existence of a solution for the Cauchy problem

\[ x' \in -\partial \varphi (x) + F (x) + f (t, x), \quad x (0) = x_0, \]

where ϕ is a ϕ-convex function of order r = 2, F is an upper semicontinuous and cyclically
monotone multifunction and f is a Carathéodory function.

The particular case of a reflection problem, i.e., with ϕ = IE, was extended to that of moving
domains E(t), t ≥ 0, by considering the following problem (which solution is called sweeping
process):

\[
\begin{align*}
&x' (t) + N_{E(t)} (x(t)) \ni f (t, x(t)), \quad t \geq 0, \\
&x (0) = x_0.
\end{align*}
\]

where \( N_{E(t)} (x(t)) = \partial I_{E(t)} (x(t)) \) is the external normal cone to \( E(t) \) in \( x(t) \).

This problem was introduced by J.J. Moreau (see [29]) for the case \( f \equiv 0 \) and convex sets
\( E(t), t \geq 0 \), and it has been intensively studied since then by several authors; see, e.g., C. Cas-
taing [11], M.D.P. Monteiro Marques [28]. For the case of a sweeping process without the
assumption of convexity on the sets \( E(t), t \geq 0 \), we refer to [3,4,16,18]. The extension to the case
\( f \not\equiv 0 \) was considered, e.g., in C. Castaing, M.D.P. Monteiro Marques [12] and J.F. Edmond,
and L. Thibault [21] (see also the references therein). Another extension was made in [27] and [34]
by considering the quasivariational sweeping process

\[
\begin{align*}
&x' (t) (x(t)) \ni f (t, x(t)), \quad t \geq 0, \\
&x (0) = x_0.
\end{align*}
\]

The works mentioned above concern the case with vanishing driving force \( m = 0 \). Let us discuss
now the case of equation (2) with singular input \( dm/dt \). The associated reflection problem with
singular input \( dm/dt \) has been investigated by A.V. Skorohod in [39] and [40] (for the particular
case of \( E = [0, \infty) \)), by H. Tanaka in [41] (for a general convex domain \( E \)), and by P.-L. Lions
and A.S. Sznitman in [24] and Y. Saisho in [38] for a non-convex domains. Generalizations from
the reflection problem (with \( \partial \varphi = \partial I_E \)) to the case of \( \partial \varphi \) for a general convex function \( \varphi \), and
even to the case of a maximal monotone operator $A$, were discussed by A. Răşcanu in [32], V. Barbu and A. Răşcanu in [2] and by E. Cépa in [13] and [14].

More recently, A.M. Gassous, A. Răşcanu and E. Rotenstein obtained in [22] existence and uniqueness results for stochastic variational inequalities with oblique subgradients. More precisely, in their equation the direction of reflection at the boundary of the convex domain differs from the normal direction, an effect which is caused by the presence of a multiplicative Lipschitz matrix acting on the subdifferential operator. In the authors’ approach it turned out to be crucial to pass first by a study of the Skorohod problem with generalized reflection.

The objective of the present work is twofold: We generalize both the (non-)convex reflection problem as well as convex variational inequalities to non-convex variational inequalities. Some studies in this direction have been made already by A. Răşcanu and E. Rotenstein in [33]: a non-convex setup for multivalued (deterministic) differential equations driven by oblique subgradients has been established and the uniqueness and the local existence of the solution has been proven.

Our approach here in the present manuscript is heavily based on an a priori discussion of the generalized Skorohod problem (2) with $f \equiv 0$ and a $(\rho, \gamma)$-semiconvex $\varphi$. We give useful a priori estimates and prove the existence and the uniqueness of a solution $(x, k)$ for the generalized Skorohod problem:

\[
\begin{align*}
    x(t) + k(t) &= x_0 + m(t), & t \geq 0, \\
    dk(t) &\in \partial^{-}\varphi(x(t))(dt), \\
\end{align*}
\]

where $x_0 \in \overline{\text{Dom}}(\varphi)$, the input $m$ is a continuous function starting from zero, and $\partial^{-}\varphi$ is the Fréchet subdifferential of a proper, lower semicontinuous and $(\rho, \gamma)$-semiconvex function $\varphi$. Here the set $\text{Dom}(\varphi)$ is not necessarily convex, but however two assumptions are required:

1. $\text{Dom}(\varphi)$ satisfies the uniform exterior ball condition (see Definition 1);
2. $\text{Dom}(\varphi)$ satisfies the $(\gamma, \delta, \sigma)$-shifted uniform interior ball condition, i.e.

there are some suitable constants $\gamma \geq 0$ and $\delta, \sigma > 0$ such that, for all $y \in \text{Dom}(\varphi)$, there are some $\lambda_y \in (0, 1]$ and $v_y \in \mathbb{R}^d$, $|v_y| \leq 1$ with $\lambda_y - (|v_y| + \lambda_y)^2 \gamma \geq \sigma$ and

\[
\overline{B}(x + v_y, \lambda_y) \subset \text{Dom}(\varphi), \quad \text{for all } x \in \text{Dom}(\varphi) \cap \overline{B}(y, \delta).
\]

We observe that this condition is fulfilled if, in particular, the domain $\text{Dom}(\varphi)$ satisfies the uniform interior drop condition (see Definition 5). It is worth pointing out that the shifted uniform interior ball condition is comparable with assumption (5) of P.-L. Lions, A.S. Sznitman [24] (or Condition (B) from [38]) (see the Remarks 20–21).

The application $m \mapsto x : C([0, T]; \mathbb{R}^d) \rightarrow C([0, T]; \mathbb{R}^d)$, which associates to the input function $m$ the solution $x$ of (3), will be proven to be continuous. This allows to derive the existence of a solution to the associated stochastic equation with additive noise $M = (M_t)$:

Please cite this article in press as: R. Buckdahn et al., Stochastic variational inequalities on non-convex domains, J. Differential Equations (2015), http://dx.doi.org/10.1016/j.jde.2015.08.023
\[
\begin{aligned}
X_t(\omega) + K_t(\omega) &= \xi(\omega) + M_t(\omega), \quad t \geq 0, \quad \omega \in \Omega, \\
dK_t(\omega) &\in \partial^\pm \varphi(X_t(\omega)) (dt).
\end{aligned}
\] (4)

After having the existence, the uniqueness and properties for the equations (3) and (4), we will be able to extend the study to the more general equations (2) and (1), where \( f \) (respectively \( F \)) is continuous, satisfies a one-sided Lipschitz condition with respect to the second variable and a boundedness assumption.

The article is organized as it follows: The next section is devoted to a recall of such basic notions as those of a semiconvex set, a \( (\rho, \gamma) \)-semiconvex function or a Fréchet subdifferential. Some notions, like for instance that of a \( (\rho, \gamma) \)-semiconvex function, are illustrated by an example. In Section 3 we give the definition of the solution to the generalized Skorohod problem (3), we prove the existence and the uniqueness of a solution \( (x, k) \) and we give some useful a priori estimations. Moreover, we extend equation (3) to the stochastic case (4). Section 4 is devoted to the proof of the both main results of Section 3. Finally, the Sections 5 and 6 study the extension of the results established in Section 3 to the equations (2) and (1). Appendix A is devoted to important auxiliary results such as applications of Fatou’s Lemma, some complements concerning tightness in \( C([0,1]; \mathbb{R}^d) \) or a very useful forward stochastic inequality, which are used in our approach.

2. Preliminaries

We introduce first some definitions and results concerning the notions of normal cone, uniform exterior ball conditions, semiconvex sets, \( (\rho, \gamma) \)-semiconvex functions and Fréchet subdifferential of a function.

Here and everywhere below \( E \) will be a nonempty closed subset of \( \mathbb{R}^d \). Let \( N_E(x) \) be the closed external normal cone of \( E \) at \( x \in \text{Bd}(E) \) i.e.

\[
N_E(x) := \left\{ u \in \mathbb{R}^d : \lim_{\delta \downarrow 0} \frac{d_E(x + \delta u)}{\delta} = |u| \right\},
\]

where \( d_E(z) := \inf \{|z - x| : x \in E\} \) is the distance of a point \( z \in \mathbb{R}^d \) to \( E \).

**Definition 1.** Let \( r_0 > 0 \). We say that \( E \) satisfies the \( r_0 \)-uniform exterior ball condition (we write it \( r_0\text{-UEBC} \) for brevity) if

\[ B(x + u, r_0) \cap E = \emptyset, \quad \text{where } B(x, r) \text{ denotes the ball from } \mathbb{R}^d \text{ of center } x \text{ and radius } r \]

or equivalently if

\[ N_E(x) \neq \{0\} \quad \text{for all } x \in \text{Bd}(E) \]

and

\[ \text{for all } x \in \text{Bd}(E) \text{ and } u \in N_E(x) \text{ such that } |u| = r_0 \text{ it holds that } d_E(x + u) = r_0. \]

We remark that for all \( v \in N_E(x) \) with \( |v| \leq r_0 \) we also have \( d_E(x + v) = |v| \).
Definition 2. Let $\gamma \geq 0$. A set $E$ is $\gamma$-semiconvex if for all $x \in \text{Bd}(E)$ there exists $\hat{x} \in \mathbb{R}^d \setminus \{0\}$ such that

$$\langle \hat{x}, y - x \rangle \leq \gamma \|\hat{x}\| |y - x|^2, \quad \forall y \in E.$$  

We have the following equivalence:

Lemma 3. (See [31, Lemma 6.47].) Let $r_0 > 0$. The set $E$ satisfies the $r_0$-UEBC if and only if $E$ is $\frac{1}{2r_0}$-semiconvex.

For a given $z \in \mathbb{R}^d$ we denote by $\Pi_E(z)$ the set of elements $x \in E$ such that $d_E(z) = |z - x|$. Obviously, $\Pi_E(z)$ is nonempty since $E$ is nonempty and closed. Moreover, under the $r_0$-uniform exterior ball condition, it follows that the set $\Pi_E(z)$ is a singleton for all $z$ such that $d_E(z) < r_0$. In this case $\pi_E(z)$ will denote the unique element of $\Pi_E(z)$ and it is called the projection of $z$ on $E$. We recall the following well-known property of the projection.

Lemma 4. Let the $r_0$-UEBC be satisfied, $\varepsilon \in (0, r_0)$ and $\overline{U}_\varepsilon(E) := \{y \in \mathbb{R}^d : d_E(y) \leq \varepsilon\}$ denoting the closed $\varepsilon$-neighborhood of $E$.

Then:

- the closed external normal cone of $E$ at $x$ is given by

$$N_E(x) = \left\{ \hat{x} : \langle \hat{x}, y - x \rangle \leq \frac{1}{2r_0} |\hat{x}| |y - x|^2, \forall y \in E \right\};$$

- the projection $\pi_E$ restricted to $\overline{U}_\varepsilon(E)$ is Lipschitz with Lipschitz constant $L_\varepsilon = r_0/(r_0 - \varepsilon)$;

and

- the function $d_E^2(\cdot)$ is of class $C^1$ on $\overline{U}_\varepsilon(E)$ with

$$\frac{1}{2} \nabla d_E^2(z) = z - \pi_E(z) \quad \text{and} \quad z - \pi_E(z) \in N_E(\pi_E(z)), \forall z \in \overline{U}_\varepsilon(E).$$

Let us introduce now the notion of drop of vertex $x$ and running direction $v$.

Let $x, v \in \mathbb{R}^d$, $r > 0$. The set

$$D_x(v, r) := \text{conv}\left\{x, \overline{B}(x + v, r)\right\} = \left\{x + t(u - x) : u \in \overline{B}(x + v, r), \ t \in [0, 1] \right\}$$

is called $(v, r)$-drop of vertex $x$ and running direction $v$. Remark that if $|v| \leq r$, then $D_x(v, r) = \overline{B}(x + v, r)$.

Definition 5. The set $E \subset \mathbb{R}^d$ satisfies the uniform interior drop condition if there exist $r_0, h_0 > 0$ such that for all $x \in E$ there exists $v_x \in \mathbb{R}^d$ with $|v_x| \leq h_0$ and

$$D_x(v_x, r_0) \subset E$$

(we also say that $E$ satisfies the uniform interior $(h_0, r_0)$-drop condition).
Remark 6. It is easy to see that if there exists \( r_0 > 0 \) such that \( E^c \) satisfies the \( r_0 \)-\( UEBC \), then \( E \) satisfies the uniform interior \((h_0, r_0)\)-drop condition.

Indeed let \( x \in Bd(E^c) = Bd(E) \) and \( u_x \in N_{E^c}(x) \) with \( |u_x| = r_0 \).

Then

\[
D_x(u_x, r_0/2) \subseteq D_x(u_x, r_0) = \overline{B}(x + u_x, r_0) \subseteq E.
\]

It is easy to see that, for any \( x \in int(E) \), there exists a direction \( v_x \in \mathbb{R}^d \) such that \( |v_x| \leq r_0 \) and 
\[
D_x(v_x, r_0/2) \subseteq E.
\]

We state below that the drop condition implies a weaker condition, but is not equivalent with this (for the proof see Proposition 4.35 in [31]).

Proposition 7. Let the set \( E \) be as above with \( Int(E) \neq \emptyset \). If set \( E \) satisfies the uniform interior \((h_0, r_0)\)-drop condition then \( E \) satisfies the shifted uniform interior ball condition, which means
that there exist \( \gamma \geq 0 \) and \( \delta, \sigma > 0 \), and for every \( y \in E \) there exist \( \lambda_y \in (0, 1] \) and \( v_y \in \mathbb{R}^d \),
\[
|v_y| \leq 1 \quad \text{such that}
\]

\[
(i) \quad \lambda_y - (|v_y| + \lambda_y)^2 \gamma \geq \sigma,
(ii) \quad \overline{B}(x + v_y, \lambda_y) \subseteq E, \quad \forall \, x \in E \cap \overline{B}(y, \delta)
\]

(this condition will be called \((\gamma, \delta, \sigma)\)-SUIBC).

Example 8. Let \( E \) be a set for which there exists a function \( \phi \in C^2_b(\mathbb{R}^d) \) such that

\[
(i) \quad E = \{ x \in \mathbb{R}^d : \phi(x) \leq 0 \},
(ii) \quad Int(E) = \{ x \in \mathbb{R}^d : \phi(x) < 0 \},
(iii) \quad Bd(E) = \{ x \in \mathbb{R}^d : \phi(x) = 0 \} \quad \text{and} \quad |\nabla \phi(x)| = 1, \quad \forall \, x \in Bd(E).
\]

Then the set \( E \) satisfies the uniform exterior ball condition and the uniform interior drop condition.

Indeed, using the definition of \( E \) we see that, for \( x \in Bd(E) \), the gradient \( \nabla \phi(x) \) is a unit normal vector to the boundary, pointing towards the exterior of \( E \). Therefore, for any \( x \in Bd(E) \), the normal cone is given by \( N_E(x) = \{c\nabla \phi(x) : c \geq 0\} \) and \( N_{E^c}(x) = \{-c\nabla \phi(x) : c \geq 0\} \).

Since \( \phi(y) \leq 0 = \phi(x) \), for all \( y \in E, \, x \in Bd(E) \),

\[
\langle \nabla \phi(x), y - x \rangle = \phi(y) - \phi(x) - \int_0^1 \langle \nabla \phi(x + \lambda (y - x)) - \nabla \phi(x) , y - x \rangle \, d\lambda 
\]

\[
\leq M |y - x|^2 = M |\nabla \phi(x)||y - x|^2,
\]

which means, using Definition 2 and Lemma 3, that \( E \) satisfies \( \frac{1}{2M} \)-\( UEBC \).
Since \( \phi (y) \geq 0 = \phi (x) \), for all \( y \in E^c, x \in \text{Bd} (E) \),
\[
-\langle \nabla \phi (x), y-x \rangle = -\phi (y) + \int_0^1 \langle \nabla \phi (x + \lambda (y-x)), y-x \rangle d\lambda
\leq M |y-x|^2 = M |\nabla \phi (x)||y-x|^2,
\]
which yields that \( E^c \) satisfies \( \frac{1}{2M} \)-UEBC and consequently (see Remark 6) \( E \) satisfies the uniform interior drop condition.

If \( E \) denotes a closed subset of \( \mathbb{R}^d \) let \( E_\varepsilon \) be the \( \varepsilon \)-interior of \( E \), i.e.
\[
E_\varepsilon := \{ x \in E : d_{E^c} (x) \geq \varepsilon \}.
\]

**Example 9.** Let \( E \subset \mathbb{R}^d \) be a closed convex set with nonempty interior. If there exists \( r_0 > 0 \) such that (the \( r_0 \)-interior of \( E \)) \( E_{r_0} \neq \emptyset \) and \( h_0 = \sup_{z \in E} d_{E_{r_0}} (z) < \infty \) (in particular if \( E \) is a bounded closed convex set with nonempty interior), then \( E \) satisfies the uniform interior (\( h_0, r_0 \))-drop condition.

Moreover for every \( 0 < \delta \leq \frac{r_0}{2(1+h_0)} \land 1 \), \( E \) satisfies \((\gamma', \delta, \sigma)\)-SUIBC with \( \lambda_y = \sigma = \delta \).

For the proof, let \( y \in E \), \( \hat{y} \) the projection of \( y \) on the set \( E_{r_0} \) and \( v_y = \frac{1}{r_0} (\hat{y} - y) \). Hence
\[
|\hat{y} - y| \leq h_0, \ |v_y| \leq 1 \text{ and for all } x \in E \cap \overline{B} (y, \delta)
\]
\[
\overline{B} (x + v_y, \delta) \subset \overline{B} (y + v_y, r_0) \subset \text{conv} \{ y, \overline{B} (\hat{y}, r_0) \} = D_y (\hat{y} - y, r_0) \subset E.
\]

Let \( \varphi : \mathbb{R}^d \to (-\infty, +\infty] \) be a function with domain defined by
\[
\text{Dom}(\varphi) := \{ v \in \mathbb{R}^d : \varphi (v) < +\infty \}.
\]

We recall now the definition of the Fréchet subdifferential (for this kind of subdifferential operator see, e.g., [26] and the monograph [35, cap. VIII]):

**Definition 10.** The Fréchet subdifferential \( \partial^- \varphi \) is defined by:

\[ a_1 \] \( \partial^- \varphi (x) = \emptyset \), if \( x \notin \text{Dom}(\varphi) \) and
\[ a_2 \] for \( x \in \text{Dom}(\varphi) \),
\[
\partial^- \varphi (x) = \{ \hat{x} \in \mathbb{R}^d : \liminf_{y \to x} \frac{\varphi (y) - \varphi (x) - \langle \hat{x}, y-x \rangle}{|y-x|} \geq 0 \}.
\]

Taking into account this definition we will say that \( \varphi \) is proper if the domain \( \text{Dom}(\varphi) \neq \emptyset \) and has no isolated points.

We set
\[
\text{Dom}(\partial^- \varphi) := \{ x \in \mathbb{R}^d : \partial^- \varphi (x) \neq \emptyset \},
\]
\[
\partial^- \varphi = \{ (x, \hat{x}) : x \in \text{Dom}(\partial^- \varphi), \hat{x} \in \partial^- \varphi (x) \}.
\]
In the particular case of the indicator function of the closed set \( E \),
\[
\varphi (x) = I_E (x) := \begin{cases} 
0, & \text{if } x \in E, \\
+\infty, & \text{if } x \notin E,
\end{cases}
\]
the function \( \varphi \) is lower semicontinuous and the Fréchet subdifferential becomes
\[
\partial^- I_E (x) = \left\{ \hat{x} \in \mathbb{R}^d : \limsup_{y \to x, y \in E} \frac{\langle \hat{x}, y - x \rangle}{|y - x|^2} \leq 0 \right\}.
\]
Moreover, in this particular case we deduce that, for any closed subset \( E \) of a Hilbert space,
\[
\partial^- I_E (x) = N_E (x)
\]
(for the proof see Colombo and Goncharov [17]).

**Definition 11.** Let \( \rho, \gamma \geq 0 \). The function \( \varphi : \mathbb{R}^d \to (-\infty, +\infty] \) is said to be \((\rho, \gamma)\)-semiconvex function if

1. \( \text{Dom}(\varphi) \) is \( \gamma \)-semiconvex,
2. \( \text{Dom}(\partial^- \varphi) \neq \emptyset \),
3. For all \((x, \hat{x}) \in \partial^- \varphi \) and \( y \in \mathbb{R}^d \):
\[
\langle \hat{x}, y - x \rangle + \varphi (x) \leq \varphi (y) + (\rho + \gamma |\hat{x}|) |y - x|^2.
\]

**Remark 12.** Let \( E \) be a nonempty closed subset of \( \mathbb{R}^d \). We have:

1. \( I_E \) is \((0, \gamma)\)-semiconvex iff \( E \) is \( \gamma \)-semiconvex (see (6) and Definitions 2 and 11; we also mention that in the definition of \( \gamma \)-semiconvexity we can take \( x \in E \), but in this case \( \hat{x} \) should be taken 0).
2. \( I_E \) is \((0, \gamma)\)-semiconvex (or, see [26, Definition 4.1], \( \phi \)-convex of order \( r = 1 \) with \( \phi(x, y, \varphi(x), \varphi(y), \alpha) = \gamma |\alpha| \)) iff there exist \( \delta, \mu > 0 \) such that \( x \mapsto d_E (x) + \mu |x|^2 \) is convex on \( B(y, \delta) \), for any \( y \in E \) (see [31, Lemma 6.47]).
3. A convex function is also \((\rho, \gamma)\)-semiconvex function, for any \( \rho, \gamma \geq 0 \) (see Definition 11 and the definition of the subdifferential of a convex function).
4. If \( E \) is convex, then \( E \) is \( \gamma \)-semiconvex for any \( \gamma \geq 0 \) (see the supporting hyperplane Theorem 41.6 from [7]).
5. If \( E \) has nonempty interior and is 0-semiconvex, then \( E \) is convex (see Definition 2 and [8, Exercise 2.27]).
6. If \( \varphi : \mathbb{R}^d \to (-\infty, +\infty] \) is a \((\rho, \gamma)\)-semiconvex function, then there exist \( a, b \in \mathbb{R}_+ \) and \( c \in \mathbb{R} \) such that
\[
\varphi (y) + a |y|^2 + b |y|^2 + c \geq 0, \quad \text{for all } y \in \mathbb{R}^d.
\]
Indeed, by Definition 11, we have, for a fixed \((x_0, \hat{x}_0) \in \partial^- \varphi : a = \rho + \gamma |\hat{x}_0|, b = 2a |x_0|^2 + |\hat{x}_0| \) and \( c = a |x_0|^2 + |\hat{x}_0, x_0| - \varphi (x_0) \).
Example 13. If the bounded set \( E \) satisfies the \( r_0\)-UEBC and \( g \in C^1(\mathbb{R}^d) \) (or \( g : \mathbb{R}^d \to \mathbb{R} \) is a convex function), then \( \varphi : \mathbb{R}^d \to (-\infty, +\infty] \) given by
\[
\varphi(x) := I_E(x) + g(x)
\]
is a lower semicontinuous and \( \left( \frac{L}{r_0}, \frac{1}{r_0} \right) \)-semiconvex function, where \( |\nabla g(x)| \leq L \), for any \( x \in E \) (or \( |\partial g(x)| \leq L \), for any \( x \in E \)). Moreover
\[
|\varphi(x) - \varphi(y)| \leq L|x - y|, \quad \forall x, y \in \text{Dom}(\varphi) = E.
\]

In order to define the solution for the deterministic problem envisaged by our work it is necessary to introduce the bounded variation function space.

Let \( T > 0, k : [0, T] \to \mathbb{R}^d \) and \( \mathcal{D} \) be the set of the partitions of the interval \([0, T]\).

Set
\[
S_\Delta(k) = \sum_{i=0}^{n-1} |k(t_{i+1}) - k(t_i)|
\]
and
\[
\mathcal{C} \Delta \upsilon_T := \sup_{\Delta \in \mathcal{D}} S_\Delta(k), \quad (7)
\]
where \( \Delta : 0 = t_0 < t_1 < \cdots < t_n = T \).

Write
\[
BV([0, T]; \mathbb{R}^d) = \{k : [0, T] \to \mathbb{R}^d : \mathcal{C} \Delta \upsilon_T < \infty\}.
\]
The space \( BV([0, T]; \mathbb{R}^d) \) equipped with the norm \( \|k\|_{BV([0, T]; \mathbb{R}^d)} := |k(0)| + \mathcal{C} \Delta \upsilon_T \) is a Banach space.

Moreover, we have the duality
\[
(C([0, T]; \mathbb{R}^d))^* = \{k \in BV([0, T]; \mathbb{R}^d) : k(0) = 0\}
\]
given by the Riemann–Stieltjes integral
\[
(y, k) \mapsto \int_0^T \langle y(t), \, dk(t) \rangle.
\]
We will say that a function \( k \in BV_{loc}(\mathbb{R}_+; \mathbb{R}^d) \) if, for every \( T > 0, k \in BV([0, T]; \mathbb{R}^d) \).
3. Generalized Skorohod problem

The aim of this section is to prove the existence and uniqueness result for the following deterministic Cauchy type differential equation:

\[
\begin{align*}
\begin{cases}
    dx(t) + \partial^{-\varphi}(x(t))\,dt \ni dm(t), & t > 0, \\
x(0) = x_0,
\end{cases}
\end{align*}
\]

where

\[(i)\quad x_0 \in \text{Dom}(\varphi),
\]
\[(ii)\quad m \in C\left([\mathbb{R}_+^+; \mathbb{R}^d]\right), \; m(0) = 0,
\]

and

\[\varphi : \mathbb{R}^d \to (-\infty, +\infty] \text{ is a proper lower semicontinuous and } (\rho, \gamma)\text{-semiconvex function.}\]

**Definition 14** (Generalized Skorohod problem). A pair \((x, k)\) of continuous functions \(x, k : \mathbb{R}_+ \to \mathbb{R}^d\), is a solution of equation (8) if

\[(j)\quad x(t) \in \text{Dom}(\varphi), \; \forall \; t \geq 0 \text{ and } \varphi(x(\cdot)) \in L^1_{\text{loc}}(\mathbb{R}_+),
\]
\[(jj)\quad k \in BV_{\text{loc}}\left([\mathbb{R}_+^+; \mathbb{R}^d]\right), \; k(0) = 0,
\]
\[(jjj)\quad x(t) + k(t) = x_0 + m(t), \; \forall \; t \geq 0,
\]
\[(jv)\quad \forall \; 0 \leq s \leq t, \; \forall \; y : \mathbb{R}_+ \to \mathbb{R}^d \text{ continuous:}
\]
\[\int_s^t \langle y(r) - x(r), dk(r) \rangle + \int_s^t \varphi(x(r))\,dr \leq \int_s^t \varphi(y(r))\,dr
\]
\[+ \int_s^t |y(r) - x(r)|^2 (\rho dr + \gamma d\kappa r).
\]

In this case the pair \((x, k)\) is said to be the solution of the generalized Skorohod problem \((\partial^{-\varphi}; x_0, m)\) (denoted by \((x, k) = \text{SP}\left(\partial^{-\varphi}; x_0, m\right)\)).

If \(\varphi = I_E\) then \(\partial^{-\varphi} = \nabla E\) and we say that \((x, k)\) is solution of the Skorohod problem \((E; x_0, m)\) and we write \((x, k) = \text{SP}\left(E; x_0, m\right)\).

**Remark 15.** The notation

\[dk(t) \in \partial^{-\varphi}(x(t))(dt)\]

means that \(x, k : \mathbb{R}_+ \to \mathbb{R}^d\) are continuous functions satisfying conditions (11-\(j, jj, jv\)).

The next result provides an equivalent condition for (11-\(jv\)) and will be used later in the proof of the continuity of the mapping \((x_0, m) \mapsto (x, k) = \text{SP}\left(\partial^{-\varphi}; x_0, m\right)\) and for the main existence result in the stochastic case.
Lemma 16. We suppose that $\varphi$ satisfies assumption (10) and let $x, k : \mathbb{R}_+ \to \mathbb{R}^d$ be two continuous functions satisfying (11-j, j). Then the pair $(x, k)$ satisfies (11-jv) if and only if there exists a continuous increasing function $A : \mathbb{R}_+ \to \mathbb{R}_+$, such that

\[
(\text{11-jv}) \quad \forall 0 \leq s \leq t, \, \forall y : \mathbb{R}_+ \to \mathbb{R}^d \text{ continuous:}
\]

\[
\int_t^s \langle y(r) - x(r), dk(r) \rangle + \int_t^s \varphi(x(r)) \, dr \leq \int_t^s \varphi(y(r)) \, dr
\]

\[
+ \int_t^s |y(r) - x(r)|^2 \, dA_r.
\]

Proof. We only need to prove that (12) $\Rightarrow$ (11-jv).

Denote

\[
Q_r := r + \downarrow k\uparrow_r + A_r
\]

and let $\lambda, \eta : \mathbb{R}_+ \to [0, 1]$ and $\theta : \mathbb{R}_+ \to \mathbb{R}^d$ with $|\theta(r)| = 1$, for any $r \in \mathbb{R}_+$, be some measurable functions (given by the Radon–Nikodym’s theorem) such that

\[
dk(r) = \theta(r) \, dQ_r, \quad dr = \lambda(r) \, dQ_r \quad \text{and} \quad dA_r = \eta(r) \, dQ_r
\]

Clearly $d\downarrow k\uparrow_r = |\theta(r)| \, dQ_r$. From (12) we deduce that, for all $t \in \mathbb{R}_+, \varepsilon > 0$ and $z \in \text{Dom} (\varphi)$

\[
\int_{t-\varepsilon}^{t+\varepsilon} \langle z - x(r), \theta(r) \rangle \, dQ_r + \int_{t-\varepsilon}^{t+\varepsilon} \varphi(x(r)) \, \lambda(r) \, dQ_r \leq \varphi(z) \int_{t-\varepsilon}^{t+\varepsilon} \lambda(r) \, dQ_r
\]

\[
+ \int_{t-\varepsilon}^{t+\varepsilon} |z - x(r)|^2 \, \eta(r) \, dQ_r
\]

and therefore

\[
\int_{t-\varepsilon}^{t+\varepsilon} \langle z, \theta(r) \rangle \, dQ_r - \int_{t-\varepsilon}^{t+\varepsilon} \langle x(r), \theta(r) \rangle \, dQ_r + \int_{t-\varepsilon}^{t+\varepsilon} \varphi(x(r)) \lambda(r) \, dQ_r \leq \varphi(z) \int_{t-\varepsilon}^{t+\varepsilon} \lambda(r) \, dQ_r
\]

\[
+ |z|^2 \int_{t-\varepsilon}^{t+\varepsilon} \eta(r) \, dQ_r - 2(z, \int_{t-\varepsilon}^{t+\varepsilon} x(r) \eta(r) \, dQ_r) + \int_{t-\varepsilon}^{t+\varepsilon} |x(r)|^2 \eta(r) \, dQ_r.
\]

Multiplying by $\frac{1}{Q((t-\varepsilon, t+\varepsilon))}$ and using the Lebesgue–Béscovitch differentiation theorem, we deduce, passing to the limit in the seven above integrals, that there exists $\Gamma_1 \subset \mathbb{R}_+$ with $\int_{\Gamma_1} dQ_r = 0$, such that for all $z \in \text{Dom} (\varphi)$ and $r \in \mathbb{R}_+ \setminus \Gamma_1$

\[
\langle z - x(r), \theta(r) \rangle + \varphi(x(r)) \lambda(r) \leq \varphi(z) \lambda(r) + |z - x(r)|^2 \eta(r)
\]
Hence, from the definition of the Fréchet subdifferential we obtain
\[
\theta (r) \in \partial^- I_{\text{Dom}(\varphi)} (x (r)) , \quad \forall r \in \Gamma_2 \setminus \Gamma_1
\]
and
\[
\frac{\theta (r)}{\lambda (r)} \in \partial^- \varphi (x (r)) , \quad \forall r \in (\mathbb{R}_+ \setminus \Gamma_2) \setminus \Gamma_1.
\]

where
\[
\Gamma_2 = \{ r \geq 0 : \lambda (r) = 0 \}
\]
with
\[
\int_{\Gamma_2} \lambda (r) dQ_r = 0.
\]

Since \( I_{\text{Dom}(\varphi)} \) is \((0, \gamma)\)-semiconvex,
\[
\langle y (r) - x (r), \theta (r) \rangle \leq \gamma |\theta (r)| |y (r) - x (r)|^2 , \quad \forall r \in \Gamma_2 \setminus \Gamma_1.
\]

On the other hand, since \( \varphi \) is a \((\rho, \gamma)\)-semiconvex function, we have for any continuous \( y : \mathbb{R}_+ \rightarrow \mathbb{R}^d \),
\[
\langle y (r) - x (r), \theta (r) \rangle + \varphi (x (r)) \lambda (r) \leq \varphi (y (r)) \lambda (r)
\]
\[
+ |y (r) - x (r)|^2 (\rho \lambda (r) + \gamma |\theta (r)|),
\]
\[\forall r \in (\mathbb{R}_+ \setminus \Gamma_2) \setminus \Gamma_1.
\]

Therefore (with the convention \( 0 \cdot (+\infty) = 0 \)) we deduce that, for all \( r \in \mathbb{R}_+ \setminus \Gamma_1 \),
\[
\langle y (r) - x (r), \theta (r) \rangle \leq \gamma |\theta (r)| |y (r) - x (r)|^2 , \quad \forall r \in (\mathbb{R}_+ \setminus \Gamma_2) \setminus \Gamma_1.
\]

Integrating on \([s, t]\) with respect to the measure \( dQ_r \) we infer that (11-\( jv \)) holds. \( \square \)

**Lemma 17.** If \( dk (t) \in \partial^- \varphi (x (t)) (dt) \) and \( \hat{d}k (t) \in \partial^- \varphi (\hat{x} (t)) (dt) \), then for all \( 0 \leq s \leq t \):

\[
\int_s^t \left[ x (r) - \hat{x} (r) \right]^2 \left( 2\rho \sigma r + \gamma \sigma \delta r \right) + \int_s^t \left[ x (r) - \hat{x} (r) \right] \left( dk (r) - \hat{d}k (r) \right) \geq 0.
\]

**Proof.** The conclusion follows from (11-\( jv \)) written for \((x, k)\) with \( y = \hat{x} \) and for \((\hat{x}, \hat{k})\) with \( y = x \). \( \square \)

**Notation 18.** Let \( \| x \|_{[s, t]} := \sup_{r \in [s, t]} |x_r| \) and \( \| x \|_t := \| x \|_{[0, t]} \).

**Theorem 19 (Uniqueness).** Let assumptions (9) and (10) be satisfied. If \((x, k) = SP (\partial^- \varphi; x_0, m) \) and \((\hat{x}, \hat{k}) = SP (\partial^- \varphi; \hat{x}_0, \hat{m}) \) then for all \( t \geq 0 \):
\[ \| x - \hat{x} \|_t^2 \leq 2 \left( \| x_0 - \hat{x}_0 \| + \| m - \hat{m} \| + 2 \| m - \hat{m} \|_t \| k - \hat{k} \|_t \right) \]
\[ \cdot \exp(8\rho t + 4\gamma \frac{\| k - \hat{k} \|}{\| k - \hat{k} \|_t}) \]  
(15)

In particular the uniqueness of the problem \( SP(\partial \varphi; x_0, m) \) follows.

**Proof.** We clearly have
\[ \| x(t) - m(t) - \hat{x}(t) + \hat{m}(t) \|_t^2 \leq \| x_0 - \hat{x}_0 \|_t^2 \]
\[ + 2 \int_0^t \langle m(r) - \hat{m}(r), dk(r) - d\hat{k}(r) \rangle - 2 \int_0^t \langle x(r) - \hat{x}(r), dk(r) - d\hat{k}(r) \rangle \]

Using (14) it follows that
\[ \frac{1}{2} \| x(t) - \hat{x}(t) \|_t^2 - \| m(t) - \hat{m}(t) \|_t^2 \leq \| x(t) - m(t) - \hat{x}(t) + \hat{m}(t) \|_t^2 \]
\[ \leq \| x_0 - \hat{x}_0 \|_t^2 + 2 \| m - \hat{m} \|_t \frac{\| k - \hat{k} \|}{\| k - \hat{k} \|_t} \]
\[ + 2 \int_0^t \langle x(r) - \hat{x}(r), r \rangle \left( 2\rho d\rho + \gamma d\gamma \frac{k}{\| k \|_r} + \gamma d\gamma \frac{\hat{k}}{\| k \|_r} \right), \]

which implies, via Gronwall’s inequality, the desired conclusion. \( \square \)

To derive the uniform boundedness and the continuity of the solution of the generalized Skorohod problem we need to introduce some additional assumptions:
\[ |\varphi(x) - \varphi(y)| \leq L + L|x - y|, \forall x, y \in Dom(\varphi) \]  
(16)

and

\( Dom(\varphi) \) satisfies the \((\gamma, \delta, \sigma)\)-shifted uniform interior ball condition  
(17)

(for the definition of \((\gamma, \delta, \sigma)\)-SUIBC, see definition (5)).

We mention that assumption (16) is obviously satisfied by the function \( \varphi \) given in the Example 13.

Using Proposition 7 we see that assumption (17) is fulfilled if we impose that
\( Dom(\varphi) \) satisfies the \((h_0, r_0)\)-drop condition,  
(18)

condition which can be more easily visualized.

Note that the lower semicontinuity of \( \varphi \) and the assumption (16) clearly yield that the \( Dom(\varphi) \)

is a closed set, and, from the assumption (17) it can be derived that

\( Int(Dom(\varphi)) \neq \emptyset. \)
Remark 20. Technical condition (5) from assumption (17) will provide an estimate for the total variation of \( k \) (see Lemma 29). On the other hand, assumption (5) from P.-L. Lions and A.S. Sznitman [24] (or [38, Condition (B)]) has the same role (see [24, Lemma 1.2]).

In the particular case \( \varphi = I_E \), as in [24], it is essentially used in the representation of the bounded variation process \( k \) and in our case it is used in the subdifferential inequality (11-\( j_v \)). Hence assumption (17) is required by the transition from the particular case of the indicator function to the case of a general convex l.s.c. function \( \varphi \).

Remark 21. We notice that assumption (18) is similar to Condition (B’) from [38] (the uniform interior cone condition). But the running direction from the drop condition (18) is not required to be uniform with respect to the vertex, like in [38, Condition (B’)].

In order to prove some a priori estimates, let us introduce the following notation: for \( y \in C ([0, T]; \mathbb{R}^d) \) and \( \varepsilon > 0 \) write

\[
\mu_y (\varepsilon) = \varepsilon + m_y (\varepsilon),
\]

where \( m_y (\varepsilon) \) is the modulus of continuity, given by

\[
m_y (\varepsilon) := \sup \{ |y(t) - y(s)| : |t - s| \leq \varepsilon, \ t, s \in [0, T] \}.
\]

The function \( \mu_y : [0, T] \to [0, \mu_y (T)] \) is a strictly increasing continuous function and therefore the inverse function \( \mu_y^{-1} : [0, \mu_y (T)] \to [0, T] \) is well defined and is also a strictly increasing continuous function. Using this inverse function let \( C \) be a positive constant and

\[
\begin{align*}
\Delta_m &:= 1/\mu_y^{-1} (\delta^2 \exp[-C (1 + T + \|m\|_T)]) , \\
C_{T,m} &:= \exp[C (1 + T + \|m\|_T + \Delta_m)].
\end{align*}
\]

Remark 22. It is easy to prove that, for any compact subset \( \mathcal{M} \subset C ([0, T]; \mathbb{R}^d) \),

\[
\Delta_{\mathcal{M}} := \sup_{m \in \mathcal{M}} \Delta_m < \infty \quad \text{and} \quad C_{T,\mathcal{M}} := \sup_{m \in \mathcal{M}} C_{T,m} < \infty.
\]

The main results of this section are the following two theorems whose proofs will be given in the next section:

Theorem 23. Let assumptions (9), (10), (16) and (17) be satisfied. Then there exists a constant \( C \), depending only on the constants from the assumptions, such that if \( (x, k) = \mathcal{SP}(\partial^- \varphi; x_0, m) \) then

\[
\begin{align*}
(a) \quad & \|k\|_{BV ([0, T]; \mathbb{R}^d)} = \varepsilon + \|m\|_T \leq C_{T,m}, \\
(b) \quad & \|x\|_T \leq |x_0| + C_{T,m}, \\
(c) \quad & |x(t) - x(s)| + k\downarrow t + k\downarrow s \leq C_{T,m} \sqrt{\mu_y (t - s)}, \quad \forall 0 \leq s \leq t \leq T.
\end{align*}
\]

If moreover \( \tilde{m} \in C ([0, T]; \mathbb{R}^d) \), \( \tilde{x}_0 \in \text{Dom}(\varphi) \) and \( (\tilde{x}, \tilde{k}) = \mathcal{SP}(\partial^- \varphi; \tilde{x}_0, \tilde{m}) \), then

\[
\|x - \tilde{x}\|_T + \|k - \tilde{k}\|_T \leq A \left( C_{T,m}, C_{T,\tilde{m}} \right) \left[ \|x_0 - \tilde{x}_0\| + \sqrt{\|m - \tilde{m}\|_T} \right],
\]

where \( A \) is a continuous function.
We can now derive the following continuity result of the mapping \((x_0, m) \mapsto (x, k) = SP(\partial^- \varphi; x_0, m)\).

**Corollary 24.** Let assumptions (9), (10), (16) and (17) be satisfied. If \(x_{0n}, x_0 \in \overline{\text{Dom}}(\varphi)\), \(m_n, m \in C(\mathbb{R}_+; \mathbb{R}^d)\), \(m_n(0) = 0\) and

1. \((x_n, k_n) = SP(\partial^- \varphi; x_0, m_n)\).
2. \(x_{0n} \to x_0\).
3. \(m_n \to m\) in \(C([0, T]; \mathbb{R}^d)\), \(\forall T \geq 0\),

then

\[
\sup_{n \in \mathbb{N}^+} \|k_n\|_T < \infty, \forall T \geq 0,
\]

and there exist \(x, k \in C(\mathbb{R}_+; \mathbb{R}^d)\) such that, for any \(T \geq 0\),

\[
(a) \quad \|x_n - x\|_T + \|k_n - k\|_T \to 0,
\]

\[
(b) \quad (x, k) = SP(\partial^- \varphi; x_0, m).
\]

**Proof.** Let us fix arbitrary \(T > 0\). The set \(\mathcal{M} = \{m, m_n : n \in \mathbb{N}^*\}\) is a compact subset of \(C([0, T] ; \mathbb{R}^d)\). If \(C_{T,m}\) is the constant defined by (19), then, using (20), it follows that

\[
C_{T,\mathcal{M}} := \sup_{v \in \mathcal{M}} C_{T,v} < \infty.
\]

Also

\[
\mu_{\mathcal{M}}(\varepsilon) := \sup_{v \in \mathcal{M}} \mu_v(\varepsilon) \searrow 0, \text{ as } \varepsilon \searrow 0.
\]

Let \(a > 0\) be such that \(|x_{0n}| \leq a\). By the estimates established in Theorem 23 we obtain: for all \(n, l \in \mathbb{N}^*\) and for all \(s, t \in [0, T], s \leq t\),

\[
\|x_n\|_T + \|k_n\|_T \leq a + C_{T,\mathcal{M}},
\]

\[
|x_n(t) - x_n(s)| + \|k_n\|_T \leq C_{T,\mathcal{M}} \cdot \sqrt{\mu_{\mathcal{M}}(t - s)}
\]

and

\[
\|x_n - x_l\|_T + \|k_n - k_l\|_T \leq C_{T,\mathcal{M}} \cdot \left[|x_{0n} - x_{0l}| + \sqrt{||m_n - m_l||_T}\right].
\]

Therefore there exist \(x, k, A \in C(\mathbb{R}_+; \mathbb{R}^d)\) such that

\[
x_n \to x, \quad k_n \to k, \quad \text{in } C([0, T]; \mathbb{R}^d), \text{ as } n \to \infty,
\]

and, by Arzelà–Ascoli’s theorem, on a subsequence denoted also with \(\downarrow k_n\),

\[
\downarrow k_n \to A, \text{ in } C([0, T]; \mathbb{R}^d), \text{ as } n \to \infty,
\]

where \(A\) is an increasing function starting from zero.
Clearly, the pair \((x,k)\) satisfies (11-\(j, jj, jjj\)) and (12), which means, using Lemma 16, that \((x,k) = SP(\partial^\sim \varphi; x_0, m)\). □

**Theorem 25.** Let assumptions (9), (10), (16) and (17) be satisfied.

Then the generalized Skorohod problem

\[
\begin{cases}
    x(t) + k(t) = x_0 + m(t), & t \geq 0, \\
    dk(t) \in \partial^\sim \varphi(x(t))(dt)
\end{cases}
\]

has a unique solution \((x,k)\), in the sense of Definition 14 (and we write \((x,k) = SP(\partial^\sim \varphi; x_0, m)\)).

Before giving the proof of the main results, Theorems 23 and 25, let us examine the particular case of the indicator function of the closed set \(E\) (which yields the classical Skorohod problem).

If \(E\) satisfies the \(r_0\)-UEBC, then, by Lemmas 3 and 4 and Definition 11, the set \(E\) is \(\frac{1}{2r_0}\)-semiconvex and the indicator function \(I_E(x)\) is a \((0, \frac{1}{2r_0})\)-semiconvex function. Hence assumptions (10) and (16) are satisfied.

We write the definition of the solution of the Skorohod problem in the case of the indicator function.

**Definition 26 (Skorohod problem).** Let \(E \subset \mathbb{R}^d\) be a set satisfying the \(r_0\)-UEBC. A pair \((x,k)\) is a solution of the Skorohod problem if \(x, k : \mathbb{R}_+ \rightarrow \mathbb{R}^d\) are continuous functions and

\[
\begin{align*}
(j) & \quad x(t) \in E, \\
(jj) & \quad k \in BV_{loc}(\mathbb{R}_+; \mathbb{R}^d), \quad k(0) = 0, \\
(jjj) & \quad x(t) + k(t) = x_0 + m(t), \\
(jv) & \quad \forall 0 \leq s \leq t \leq T, \forall y \in C(\mathbb{R}_+; E) \\
& \int_s^t |y(r) - x(r)|^2 \, dk(r) \leq \frac{1}{2r_0} \int_s^t |y(r) - x(r)|^2 \, dk' (r) .
\end{align*}
\]

The following theorem is a consequence of the main existence Theorem 25.

**Theorem 27.** Let \(x_0 \in E\) and \(m : \mathbb{R}_+ \rightarrow \mathbb{R}^d\) be a continuous function such that \(m(0) = 0\). If \(E\) satisfies the \(r_0\)-UEBC, for some \(r_0 > 0\), and the shifted uniform interior ball condition, then there exists a unique solution of the Skorohod problem, in the sense of Definition 26.

Moreover, each one of the following conditions is equivalent with (23-jv):

\[
\begin{cases}
    \int_0^t 1_{x(s) \in \text{Bd}(E)} \, dk(s) = 0, \\
    k(t) = \int_0^t n_{x(s)} \, dk(s),
\end{cases}
\]

where \(n_{x(s)} \in N_E(x(s))\) and \(|n_{x(s)}| = 1\), \(dk(s) \text{ a.e.}\).
and

\[ (j\psi) \quad \exists \beta > 0 \text{ such that } \forall y : \mathbb{R}_+ \to E \text{ continuous,} \]

\[ \int_s^t \langle y(r) - x(r), dk(r) \rangle \leq \beta \int_s^t |y(r) - x(r)|^2 \, d\kappa_r . \tag{25} \]

**Proof.** The uniqueness is ensured by Theorem 25. For a direct proof it is sufficient to use inequality (15) and the next one: if \( (x, k) = SP(E; x_0, m) \) and \( (\hat{x}, \hat{k}) = SP(E; \hat{x}_0, \hat{m}) \), then from (23) we get (see also Lemma 17)

\[ \langle x(t) - \hat{x}(t), dk(t) - d\hat{k}(t) \rangle + \frac{1}{2r_0} |x(t) - \hat{x}(t)|^2 (d \kappa_r + d \hat{\kappa}_r) \geq 0. \]

The existence is due to Theorem 25 (but, for a direct proof of the existence, with condition (23-jv) replaced by (24), we refer the reader to [24]).

Proof of (24) \(\Rightarrow\) (23-jv): using Lemma 3 we see

\[ \int_s^t \langle y(r) - x(r), dk(r) \rangle = \int_s^t \langle y(r) - x(r), n_{x(r)}d \kappa_r \rangle \]

\[ = \int_s^t \langle y(r) - x(r), n_{x(r)}1_{x(r) \in Bd(E)}d \kappa_r \rangle \]

\[ \leq \frac{1}{2r_0} \int_s^t |n_{x(r)}| |y(r) - x(r)|^2 1_{x(s) \in Bd(E)}d \kappa_r \]

\[ \leq \frac{1}{2r_0} \int_s^t |y(r) - x(r)|^2 d \kappa_r . \]

Clearly (23-jv) \(\Rightarrow\) (25).

Proof of (25) \(\Rightarrow\) (24): let \([s, t]\) be an interval such that \(x(r) \in \text{Int}(E)\) for all \(r \in [s, t]\). Then there exists \(\delta = \delta_{s,t} > 0\) such that

\[ \inf_{r \in [s, t]} d_{Bd(E)}(x(r)) \geq \delta. \]

Let \(\lambda \in [0, \delta]\) and \(\alpha \in C([0, T]; \mathbb{R}^d)\) such that \(\|\alpha\|_T \leq 1\). Setting \(y(r) = x(r) + \lambda \alpha(r)\) in (25) we obtain

\[ \int_s^t \langle \alpha(r), dk(r) \rangle \leq \beta \lambda \int_s^t d \kappa_r . \]

Hence, passing to the limit, for \(\lambda \to 0\), and taking sup\(\|\alpha\|_T \leq 1\), we deduce the implication:
\[
x(r) \in \text{Int}(E), \forall r \in [s, t] \implies \mathcal{R}_r - \mathcal{R}_s = 0.
\] (26)

Let \( \ell(r) \) be a measurable function such that \( |\ell(r)| = 1, d\, \mathcal{R}_r \)-a.e. and

\[
k(t) = \int_0^t \ell(r) d\, \mathcal{R}_r.
\]

Since (25) holds for all \( 0 \leq s \leq t \), we deduce, using the Lebesgue–Besicovitch theorem, that

\[
\beta |y(r) - x(r)|^2 - (\ell(r), y(r) - x(r)) \geq 0, \quad d\, \mathcal{R}_r \text{-a.e.,}
\]

de for any \( y \in C([0, T]; E) \).

Therefore, from Lemma 4, we infer that

\[
\ell(r) \in \mathcal{N}_E(x(r)), d\, \mathcal{R}_r \text{-a.e.}
\] (27)

We have thus proved inequality (24), since we have (26) and (27).

In order to prove Theorem 25 let us first prove some auxiliary results.

Let \( (x, k) = \mathcal{S} \mathcal{P}(\tilde{a}^- \varphi; x_0, m) \) and \( y \in C(\mathbb{R}_+; E) \), where \( E = \text{Dom}(\varphi) \). From (16) and (11–1jv) we have, for all \( 0 \leq s \leq t \),

\[
\int_s^t \langle y(r) - x(r), dk(r) \rangle \leq L(t - s) + L \int_s^t |y(r) - x(r)|\, dr
\]
\[
+ \int_s^t |y(r) - x(r)|^2 (\rho\, dr + \gamma d\, \mathcal{R}_r).
\] (28)

Suppose that \( x(r) \in \text{Int}(\text{Dom}(\varphi)) \) for all \( r \in [s, t] \), and let

\[
0 < b \leq \inf_{r \in [s,t]} d_{\text{Bd}(E)}(x(r)).
\]

Write \( y(r) = x(r) + \lambda b \alpha(r) \) with \( \alpha \in C(\mathbb{R}_+; \mathbb{R}^d), \|\alpha\|_{[s,t]} \leq 1 \) and \( 0 < \lambda < 1 \). Hence the above inequality becomes, for \( \lambda = \left[ (1 + \gamma) (1 + b)^2 \right]^{-1} \)

\[
\lambda b \int_s^t \langle \alpha(r), dk(r) \rangle \leq (L + Lb)(t - s) + \lambda^2 b^2 \left[ \rho (t - s) + \gamma (\mathcal{R}_r - \mathcal{R}_s) \right]
\]
\[
\leq \left( L + Lb + \lambda^2 b^2 \rho \right)(t - s) + \frac{\lambda b}{1 + b} (\mathcal{R}_r - \mathcal{R}_s).
\]

Taking the supremum over all \( \alpha \) such that \( \|\alpha\|_{[s,t]} \leq 1 \) we see that
\[
\frac{\lambda b^2}{1 + b} (\text{δ} T_i - \text{δ} T_s) \leq \left( L + Lb + \lambda^2 b^2 \rho \right) (t - s).
\]

Consequently, the following result is proved:

**Lemma 28.** Let \( \varphi \) such that assumption (16) is satisfied and \( (x, k) = SP (\partial - \varphi; x_0, m) \). If \( x (r) \in \text{Int} (\text{Dom} (\varphi)) \), for all \( r \in [s, t] \), then there exists a positive constant \( C = C (L, \rho, \gamma, b) \) such that

\[
\text{δ} T_i - \text{δ} T_s \leq C (t - s)
\]

where

\[
0 < b \leq \inf_{r \in [s, t]} d_{Bd(E)} (x (r)).
\]

More generally we have

**Lemma 29.** Let \( \varphi \) be a \((\rho, \gamma)\)-semiconvex function and \( (x, k) = SP (\partial - \varphi; x_0, m) \). Assume that \( \varphi \) satisfies assumption (16) and set \( \text{Dom} (\varphi) \) satisfies assumption (17). If \( 0 \leq s \leq t \) and

\[
\sup_{r \in [s, t]} |x (r) - x (s)| \leq \delta,
\]

then there exists \( \sigma > 0 \) such that

\[
\text{δ} T_i - \text{δ} T_s \leq \frac{1}{\sigma} |k (t) - k (s)| + \frac{3L + 4\rho}{\sigma} (t - s).
\]  

(29)

**Proof.** Let us fix arbitrarily \( \alpha \in C \left( \mathbb{R}_+; \mathbb{R}^d \right) \) such that \( \| \alpha \|_{[s, t]} \leq 1 \). From assumptions (16)–(17), if

\[
y (r) := x (r) + v_{x(s)} + \lambda x(s) \alpha (r), \quad r \in [s, t],
\]

then \( y (r) \in E \).

Moreover

\[
|y (r) - x (r)| \leq |v_{x(s)}| + \lambda x(s) \leq 2
\]

and

\[
|\varphi (y (r)) - \varphi (x (r))| \leq 3L.
\]

From (28) we deduce that

\[
\lambda x(s) \int_s^t (\alpha (r) \cdot dk (r)) \leq - \int_s^t (v_{x(s)} \cdot dk (r)) + (3L + 4\rho) (t - s)
\]

\[
+ \gamma \int_s^t \left( |v_{x(s)}| + \lambda x(s) \right)^2 d \text{δ} r.
\]
Taking the supremum over all $\alpha$ such that $\|\alpha\|_{[x,t]} \leq 1$ we see, using also (5), that
\[
\sigma (\$k_{t} - \$k_{s}) \leq |k(t) - k(s)| + (3L + 4\rho)(t - s)
\]
and the lemma follows. □

Proof of Theorem 23. We denote by $C, C', C''$ generic constants independent of $x_0, \hat{x}_0, m, \hat{m}$ and $T$, but possibly depending on constants $L, \delta, \sigma, \rho, \gamma$ provided by the assumptions.

Step 1. Some estimates of the modulus of continuity of the function $x$.

Let $0 \leq s \leq t \leq T$.

Since
\[
|x(t) - x(s) - m(t) + m(s)| = |k(t) - k(s)| \leq \$k_{t} - \$k_{s},
\]
it follows that
\[
|x(t) - x(s)| \leq |m(t) - m(s)| + \$k_{t} - \$k_{s}.
\]

We clearly have
\[
|x(t) - x(s) - m(t) + m(s)|^2 = 2 \int_{s}^{t} \langle m(r) - m(s), dk(r) \rangle + 2 \int_{s}^{t} \langle x(s) - x(r), dk(r) \rangle.
\]

From (11–jv) written for $y(r) \equiv x(s)$ and (16) we have
\[
\int_{s}^{t} \langle x(s) - x(r), dk(r) \rangle \leq L(t - s) + L \int_{s}^{t} |x(s) - x(r)|dr + \int_{s}^{t} |x(s) - x(r)|^2 (\rho dr + \gamma d \$k_{r}).
\]

Thus, using also the inequality $\frac{1}{2} |\alpha|^2 \leq |\alpha - \beta|^2 + |\beta|^2$, we get
\[
\frac{1}{2} |x(t) - x(s)|^2 \leq |m(t) - m(s)|^2 + 2m_m (t - s) (\$k_{t} - \$k_{s}) + C(t - s)
\]
\[\quad + C \int_{s}^{t} |x(r) - x(s)|^2 (dr + d \$k_{r}),
\]
and, by Gronwall’s inequality,
\[ |x(t) - x(s)|^2 \leq [m_m^2(t-s) + m_m(t-s)(\delta k_{+t} - \delta k_{+s}) + (t-s)] \cdot \exp[C(1+t-s+\delta k_{+t} - \delta k_{+s})]. \] (30)

for all \(0 \leq s \leq t \leq T\).

**Step 2.** Estimates of the differences \(|x(t) - x(s)|\) and \(\delta k_{+t} - \delta k_{+s}\) under the assumption \(|x(t) - x(s)| \leq \delta\).

Let \(0 \leq s \leq r \leq t \leq T\) such that \(|x(t) - x(s)| \leq \delta\). From (29) we have
\[
\delta k_{+t} - \delta k_{+s} \leq C|k(t) - k(s)| + C(t-s) = C|x(t) - x(s) - m(t) + m(s)| + C(t-s) \leq C|x(t) - x(s)| + Cm_m(t-s) + C(t-s) \leq C\delta + Cm_m(t-s).
\]

Using the estimate (30), it clearly follows that
\[
|x(t) - x(s)|^2 \leq \mu_m(t-s) \exp[C(1+T+\|m\|_T)], \quad \text{for all } 0 \leq s \leq t \leq T,
\]

since \((t-s) + m_m(t-s) = \mu_m(t-s) \leq T + 2\|m\|_T\).

Hence if \(0 \leq s \leq t \leq T\) and \(|x(t) - x(s)| \leq \delta\) then
\[
|x(t) - x(s)| + \delta k_{+t} - \delta k_{+s} \leq \sqrt{\mu_m(t-s)} \cdot \exp[C(1+T+\|m\|_T)]. \] (31)

**Step 3.** Adapted time partition and local estimates.

Let the sequence given by (the definition is suggested by [24])
\[
t_0 = T_0 = 0,
T_1 = \inf\{ t \in [t_0, T] : d_{Bd(E)}(x(t)) \leq \delta/4 \},
T_1 = \inf\{ t \in [T_1, T] : |x(t) - x(T_1)| > \delta/2 \},
T_2 = \inf\{ t \in [T_1, T] : d_{Bd(E)}(x(t)) \leq \delta/4 \},
\]
\[
t_i = \inf\{ t \in [T_i, T] : |x(t) - x(T_i)| > \delta/2 \}
T_{i+1} = \inf\{ t \in [T_i, T] : d_{Bd(E)}(x(t)) \leq \delta/4 \},
\]

Clearly
\[
0 = T_0 = t_0 \leq T_1 < t_1 \leq T_2 < \cdots < t_i \leq T_{i+1} < t_{i+1} \leq \cdots \leq T.
\]

Let \(t_i \leq r \leq T_{i+1}\). Then \(x(r) \in \text{Int}(E)\) and \(d_{Bd(E)}(x(r)) \geq \delta/4\). By Lemma 28 we get
\[
|k(t) - k(s)| \leq \delta k_{+t} - \delta k_{+s} \leq C(t-s) \quad \text{for } t_i \leq s \leq t \leq T_{i+1}.
\]
Also for $t_i \leq s \leq t \leq T_{i+1}$:
\[
|x(t) - x(s)| \leq |k(t) - k(s)| + |m(t) - m(s)| \leq C(t - s) + |m(t) - m(s)|
\leq C\mu_{m}(t - s)
\]
and then
\[
|x(t) - x(s)| + \Delta k_{t} - \Delta k_{s} \leq C\mu_{m}(t - s).
\]

On each of the intervals $[T_i, t_i]$, we have
\[
|x(t) - x(s)| \leq \delta, \quad \text{for all } T_i \leq s \leq t \leq t_i.
\]
and consequently, for all $T_i \leq s \leq t \leq t_i$, inequality (31) holds.

If $T_i \leq s \leq t \leq T_{i+1}$ then
\[
|x(t) - x(s)| + \Delta k_{t} - \Delta k_{s} \leq C\mu_{m}(t - s) + \mu_{m}(t_i - s) \cdot \exp\left[C\left(1 + T + \|m\|_T\right)\right]
\leq \sqrt{\mu_{m}(t - s)} \cdot \exp\left[C\left(1 + T + \|m\|_T\right)\right].
\]
Consequently for all $i \in \mathbb{N}$ and $T_i \leq s \leq t \leq T_{i+1}$, inequality (31) holds.

**Step 4. Getting inequalities (21).**

Since $\mu_{m}^{-1} : [0, \mu_{m}(T)] \rightarrow [0, T]$ is well defined and is a strictly increasing continuous function, from
\[
\frac{\delta}{\pi} \leq |x(t_i) - x(T_i)| \leq \sqrt{\mu_{m}(t_i - T_i)} \cdot \exp\left[C\left(1 + T + \|m\|_T\right)\right],
\]
we deduce that
\[
T_{i+1} - T_i \geq \mu_{m}^{-1}\left(\frac{\delta^2}{4}\exp\left[-2C\left(1 + T + \|m\|_T\right)\right]\right)
\geq \mu_{m}^{-1}\left(\delta^2\exp\left[-2C\left(1 + T + \|m\|_T\right)\right]\right) > 0.
\]

Hence the bounded increasing sequence $(T_i)_{i \geq 0}$ has a finite number of terms, therefore there exists $j \in \mathbb{N}^\ast$ such that $T = T_j$. Then
\[
T = T_j = \sum_{i=1}^{j} (T_i - T_{i-1}) \geq j\Delta_m^{-1},
\]
where $\Delta_m := 1/\mu_{m}^{-1}\left(\delta^2\exp\left[-2C\left(1 + T + \|m\|_T\right)\right]\right)$ (see definition (19)).
Let $0 \leq s \leq t \leq T$. We have

$$\sum_{i=1}^{j} \left( \frac{\|x(t)\|}{\|m\|} \right) \leq \sum_{i=1}^{j} \left( \frac{\|x(t)\|}{\|m\|} \right) \cdot \exp \left[ C \left( 1 + T + \|m\| \right) \right]$$

and consequently

$$\frac{\|x(t)\|}{\|m\|} \leq \exp \left[ C \left( 1 + T + \|m\| \right) \right]$$

and

$$\|x(t)\| \leq C_{T,m} \cdot \|x(t)\| + C_{T,m}.$$
\[ \|x_n - x\|_T + \|k_n - k\|_T \to 0, \text{ as } n \to \infty, \text{ and} \]
\[
(x, k) = \mathcal{S}\mathcal{P} \left( \partial^{-\varphi}; x_0, m \right),
\]
which completes the proof. \[ \square \]

5. Generalized Skorohod equations

Consider the next (non-convex) variational inequality with singular input (which will be called generalized Skorohod differential equation):

\[
\begin{cases}
    x(t) + k(t) = x_0 + \int_0^t f(s, x(s)) \, ds + m(t), & t \geq 0, \\
    dk(t) \in \partial^{-\varphi}(x(t)) (dt)
\end{cases}
\]

(for the notation \(dk(t) \in \partial^{-\varphi}(x(t)) (dt)\) we recall Remark 15).

We introduce the following supplementary assumptions:

\[
f(\cdot, x) : \mathbb{R}_+ \to \mathbb{R}^d \text{ is measurable, } \forall x \in \mathbb{R}^d,
\]

and there exists \(\mu \in L^1_{\text{loc}}(\mathbb{R}_+)\), such that a.e. \(t \geq 0\):

\[
\begin{align*}
    (i) & \quad x \mapsto f(t, x) : \mathbb{R}^d \to \mathbb{R}^d \text{ is continuous,} \\
    (ii) & \quad (x - y, f(t, x) - f(t, y)) \leq \mu(t) |x - y|^2, \forall x, y \in \mathbb{R}^d, \\
    (iii) & \quad \int_0^T f^\#(s) \, ds < \infty, \forall T \geq 0,
\end{align*}
\]

where

\[
f^\#(t) := \sup \{ |f(t, x)| : x \in \overline{\text{Dom}(\varphi)} \}.
\]

Clearly, assumption \((34-iii)\) is satisfied if, as example, \(f(t, x) = f(t)\) or if \(\text{Dom}(\varphi)\) is bounded.

**Proposition 30 (Generalized Skorohod equation).** Let \(\varphi : \mathbb{R}^d \to (-\infty, \infty]\) and \(f : \mathbb{R}_+ \times \mathbb{R}^d \to \mathbb{R}^d\) be such that assumptions (9), (10), (16), (17) and (33), (34) are satisfied.

Then the generalized Skorohod equation (32) has a unique solution.

**Proof.** Let \((x, k)\) and \((\hat{x}, \hat{k})\) be two solutions. Then

\[
|x(t) - \hat{x}(t)|^2 + 2 \int_0^t \langle x(r) - \hat{x}(r), dk(r) - d\hat{k}(r) \rangle
\]
\[
= 2 \int_0^t \langle x(r) - \hat{x}(r), f(r, x(r)) - f(r, \hat{x}(r)) \rangle \, dr \leq 2 \int_0^t \mu^+(r) |x(r) - \hat{x}(r)|^2 \, dr,
\]

Please cite this article in press as: R. Buckdahn et al., Stochastic variational inequalities on non-convex domains, J. Differential Equations (2015), http://dx.doi.org/10.1016/j.jde.2015.08.023
and using Lemma 17 it follows that

\[ |x(t) - \hat{x}(t)|^2 \leq 2 \int_0^t |x(r) - \hat{x}(r)|^2 \, dA_t, \]

where

\[ A_t = 2 \rho t + \gamma \int_0^t |\hat{\kappa}(r)| \, dr. \]

Applying a Gronwall’s type inequality, we see that \( x = \hat{x} \).

Concerning the existence, we shall obtain the solution \((x, k)\) as the limit in \( C([0, T]; \mathbb{R}^d) \times C([0, T]; \mathbb{R}^d) \) of the sequence \((x_n, k_n)_{n \in \mathbb{N}}\) defined by an approximate Skorohod equation

\[
\begin{cases}
  x_n(t) = x_0, & \text{for } t < 0, \\
  x_n(t) + k_n(t) = x_0 + \int_0^t f(s, x_n(s - 1/n)) \, ds + m(t), & \text{for } t \geq 0,
  \\
  dk_n(t) \in \partial \phi(x_n(t)) \, (dt).
\end{cases}
\]

For any \( i \in \mathbb{N} \), for \( t \in \left[ \frac{i}{n}, \frac{i+1}{n} \right] \), we can write

\[ x_n(t) + \left[ k_n(t) - k_n(i/n) \right] = x_n(i/n) + \int_{i/n}^t f(s, x_n(s - 1/n)) \, ds + m(t) - m(i/n), \]

therefore by iteration over the intervals \( \left[ \frac{i}{n}, \frac{i+1}{n} \right] \) there exists (via Theorem 25) a unique pair \((x_n, k_n) = \mathcal{S}\mathcal{P}(\partial \phi; x_0, m_n)\), with

\[ m_n(t) = \int_0^t f(s, x_n(s - 1/n)) \, ds + m(t). \]

Let \( T > 0 \). If \( \mathcal{M} \) denotes the set

\[ \mathcal{M} := \{ m_n : n \in \mathbb{N}^* \}, \]

then \( \mathcal{M} \) is a relatively compact subset of \( C([0, T]; \mathbb{R}^d) \) since it is a bounded and equicontinuous subset of \( C([0, T]; \mathbb{R}^d) \).

Indeed

\[ \|m_n\|_T \leq \int_0^T f^\#(s) \, ds + \|m\|_T. \]
and, for $s < t$,

$$|m_n(t) - m_n(s)| \leq \int_s^t f^\#(r) \, dr + |m(t) - m(s)|.$$  

Then by Theorem 23 and Remark 22,

$$\|x_n\|_T + \varepsilon k_n \uparrow_T \leq |x_0| + C_{T, \mathcal{M}}$$  \hspace{1cm} (37)$$

and for all $0 \leq s \leq t$:

$$|x_n(t) - x_n(s)| + \varepsilon k_n \uparrow_t - \varepsilon k_n \downarrow_s \leq C_{T, \mathcal{M}} \sqrt{\mu_{\mathcal{M}}(t-s)},$$

where $\mu_{\mathcal{M}}(\varepsilon) := \varepsilon + \sup_{m \in \mathcal{M}} m$. Hence, by Arzelà–Ascoli’s theorem, the set $\{x_n : n \in \mathbb{N}^*\}$ is a relatively compact subset of $C([0, T]; \mathbb{R}^d)$. Let $x \in C([0, T]; \mathbb{R}^d)$ be such that, along a sequence still denoted by $\{x_n : n \in \mathbb{N}^*\}$,

$$\|x_n - x\|_T \to 0, \text{ as } n \to \infty.$$  

Then, uniformly with respect to $t \in [0, T]$,

$$m_n(t) \to \int_0^t f(s, x(s)) \, ds + m(t), \text{ as } n \to \infty,$$

and

$$k_n(t) \to k(t) = x_0 + \int_0^t f(s, x(s)) \, ds + m(t) - x(t), \text{ as } n \to \infty.$$  

Using Corollary 24 we infer that

$$(x, k) = \mathcal{S} \mathcal{P} \left( \partial^+ \varphi; x_0, \int_0^t f(s, x(s)) \, ds + m \right)$$

i.e. $(x, k)$ is a solution of problem (32). The uniqueness of the solution implies that the whole sequence $(x_n, k_n)$ is convergent to that solution $(x, k)$. The proof is completed now. \qed

**Remark 31.** As it can be seen in the above proof, assumption (34-iii) is essential in order to obtain inequality (37), i.e. the boundedness of the sequence $(x_n, k_n)_n$ defined by (36).
Remark 32. If we replace assumptions (16), (17) and (34-iii) by the hypotheses

\[ \text{Int (Dom (ϕ))} \neq \emptyset \]

and

\[ \int_0^T f^\#_R (s) \, ds < \infty, \quad \forall R, T > 0, \]

where

\[ f^\#_R (t) := \sup \{ |f (t, x)| : |x| \leq R \}, \]

then, following the calculus from the convex case (see, e.g., Remark 4.15 and Proposition 4.16 from [31]), we deduce

\[ \frac{1}{2} |x(t) - u_0|^2 + \frac{r_0}{2} \int_0^t |f (r, x(r))| \, dr \]

\[ \leq \frac{1}{4} \|x - u_0\|^2 + C_0 + C_0 \|m\|_T \]

\[ + 2 \int_0^t \mu^+ (r) \|x - u_0\|^2 \, dr + 2 \int_0^t \mu^+ (r) \|x - u_0\|^2 (\rho dr + \gamma d \|k\|_r), \]

(38)

where \( u_0 \in \mathbb{R}^d \) and \( r_0 \in [0, 1) \) are such that \( \overline{B} (u_0, r_0) \subset \text{Int (Dom (ϕ))} \).

In the convex case, namely \( \gamma = 0 \), this inequality yields the boundedness (21-a, b), but in the non-convex case \( (\gamma \neq 0) \) we cannot obtain (21-a, b).

Of course, if there exists \( R > 0 \) such that \( \text{Dom (ϕ)} \subset B (0, R) \), then \( \|x\|_T \leq R \) and from (38) we obtain \( \|k\|_T \leq C \), if \( \gamma \) is such that

\[ 0 \leq \gamma < \frac{r_0}{2 (r_0 + R + |u_0|)}. \]

If in the above proposition we take \( \phi = I_E \) we get, via Theorem 27,

Corollary 33 (Skorohod equation). Let \( x_0 \in E \) and \( m : \mathbb{R}^+ \to \mathbb{R}^d \) be a continuous function such that \( m (0) = 0 \). If \( f \) satisfies assumptions (33)–(34) and \( E \) satisfies the \( r_0 \)-UEBC (for some \( r_0 > 0 \)) and the shifted uniform interior ball condition, then there exists a unique pair \((x, k)\) such that:

\[ \begin{align*}
(j) & \quad x, k \in C (\mathbb{R}^+; E), \quad k (0) = 0, \\
(jj) & \quad k \in BV_{loc} (\mathbb{R}^+; \mathbb{R}^d), \\
(jii) & \quad x (t) + k (t) = x_0 + \int_0^t f (s, x(s)) \, ds + m (t), \\
(jiv) & \quad \|k\|_t = \int_0^t \mathbf{1}_{x(s) \in Bd (E)} d \|k\|_s, \\
(v) & \quad k (t) = \int_0^t n_{x(s)} d \|k\|_s, \quad \text{where } n_{x(s)} \in NE (x (s)) \quad \text{and} \quad |n_{x(s)}| = 1, d \|k\|_s \text{-a.e.}.
\end{align*} \]

Please cite this article in press as: R. Buckdahn et al., Stochastic variational inequalities on non-convex domains, J. Differential Equations (2015), http://dx.doi.org/10.1016/j.jde.2015.08.023
6. Non-convex stochastic variational inequalities

In the last section of the paper we will study the following multivalued stochastic differential equation (also called stochastic variational inequality) considered on a non-convex domain:

\[
X_t + K_t = \xi + \int_0^t F(s, X_s) \, ds + \int_0^t G(s, X_s) \, dB_t, \quad t \geq 0,
\]

where \( \varphi \) is \((\rho, \gamma)\)-semiconvex function and \( \{B_t : t \geq 0\} \) is an \( \mathbb{R}^k \)-valued Brownian motion with respect to a stochastic basis (which is supposed to be complete and right-continuous) \((\Omega, \mathcal{F}, \mathbb{P}, \{\mathcal{F}_t\}_{t \geq 0})\).

First we derive directly from Theorem 25 the existence result in the additive noise case.

**Corollary 34.** Let \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t)_{t \geq 0}\) be given. If

\[ \xi \in L^0(\Omega, \mathcal{F}_0, \mathbb{P}; \text{Dom}(\varphi)) \]

and \( M \) is a progressively measurable and continuous stochastic process (p.m.c.s.p. for short) with \( M_0 = 0 \), then there exists a unique pair \((X, K)\) of p.m.c.s.p., solution of the problem

\[
\begin{align*}
X_t(\omega) + K_t(\omega) &= \xi(\omega) + M_t(\omega), \quad t \geq 0, \quad \omega \in \Omega, \\
\text{d}K_t(\omega) &= \partial^- \varphi(X_t(\omega)) \, (\text{d}t),
\end{align*}
\]

(in this case we shall write \((X(\omega), K(\omega)) = \mathcal{SP}(\partial^- \varphi; \xi(\omega), M(\omega)), \mathbb{P}\text{-a.s.})

**Proof.** Let \( \omega \) be arbitrary but fixed. By Theorem 25, the Skorohod problem

\[(X(\omega), K(\omega)) = \mathcal{SP}(\partial^- \varphi; \xi(\omega), M(\omega))\]

has a unique solution

\[(X(\omega), K(\omega)) \in C([0; T]; \mathbb{R}^d) \times C([0; T]; \mathbb{R}^d).\]

Since \((\omega, t) \mapsto M_t(\omega)\) is progressively measurable and the mapping

\[(\xi, M) \mapsto X : \text{Dom}(\varphi) \times \mathbb{R}_{+} \times \mathbb{R}^d \to \mathbb{R}^d \to C([0, t]; \mathbb{R}^d) \to C([0, t]; \mathbb{R}^d)\]

is continuous for each \( 0 \leq t \leq T \), the stochastic process \( X \) is progressively measurable. Hence the conclusion follows. \( \square \)

The next assumptions will be needed throughout this section:

(A1) (Carathéodory conditions.) The functions \( F(\cdot, \cdot, \cdot) : \Omega \times \mathbb{R}_{+} \times \mathbb{R}^d \to \mathbb{R}^d \) and \( G(\cdot, \cdot, \cdot) : \Omega \times \mathbb{R}_{+} \times \mathbb{R}^d \to \mathbb{R}^{d \times k} \) are \((\mathbb{P}, \mathbb{R}^d)\)-Carathéodory functions, i.e.
\[ F ( \cdot, \cdot, x ) \text{ and } G ( \cdot, \cdot, x ) \text{ are p.m.s.p., } \forall x \in \mathbb{R}^d, \]
\[ F ( \omega, t, \cdot ) \text{ and } G ( \omega, t, \cdot ) \text{ are continuous function } d\mathbb{P} \otimes dt\text{-a.e.} \quad (41) \]

(A2) (Boundedness conditions.) For all \( T \geq 0: \)
\[ \int_0^T F^\# (s) \, ds < \infty \quad \text{and} \quad \int_0^T |G^\# (s)|^2 \, ds < \infty, \, \mathbb{P}\text{-a.s.}, \quad (42) \]
where
\[
F^\# (t) := \sup \{ |F(t,x)| : x \in \text{Dom}(\varphi) \}, \\
G^\# (t) := \sup \{ |G(t,x)| : x \in \text{Dom}(\varphi) \}
\]

(A3) (Monotonicity and Lipschitz conditions.) There exist \( \mu \in L^1_{\text{loc}}(\mathbb{R}_+) \) and \( \ell \in L^2_{\text{loc}}(\mathbb{R}_+) \) with \( \ell \geq 0, \) such that \( d\mathbb{P} \otimes dt\text{-a.e.} \)

(i) \[ \langle x - y, F(t,x) - F(t,y) \rangle \leq \mu(t) |x - y|^2, \quad \forall x, y \in \mathbb{R}^d, \]
(ii) \[ |G(t,x) - G(t,y)| \leq \ell(t) |x - y|, \quad \forall x, y \in \mathbb{R}^d. \quad (43) \]

We define now the notions of strong and weak solutions for the stochastic Skorohod equation (40).

**Definition 35.** Let \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t)_{t \geq 0}\) be given. A pair \((X, K) : \Omega \times \mathbb{R}_+ \to \mathbb{R}^d \times \mathbb{R}^d\) of continuous \(\mathcal{F}_t\)-p.m.c.s.p. is a strong solution of the stochastic Skorohod equation (40) if \(\mathbb{P}\text{-a.s.}, \)

(j) \[ X_t \in \text{Dom}(\varphi), \quad \forall t \geq 0, \quad \varphi(X_t) \in L^1_{\text{loc}}(\mathbb{R}_+), \]
(jj) \[ K \in BV_{\text{loc}}(\mathbb{R}_+; \mathbb{R}^d), \quad K_0 = 0, \]
(jjj) \[ X_t + K_t = \xi + \int_0^t F(s, X_s) \, ds + \int_0^t G(s, X_s) \, dB_s, \quad \forall t \geq 0, \]
(jv) \[ \forall 0 \leq s \leq t, \forall y : \mathbb{R}_+ \to \mathbb{R}^d \text{ continuous} \]
\[
\int_s^t \langle y(r) - X_r, dK_r \rangle + \int_s^t \varphi(X_r) \, dr \leq \int_s^t \varphi(y(r)) \, dr \\
+ \int_s^t |y(r) - X_r|^2 (\rho \, dr + \gamma d \mathbb{L} K \mathbb{L} r),
\]
which means that
\[ (X(\omega), K(\omega)) = \mathcal{S}\mathcal{P} \left( \partial^- \varphi; \xi(\omega), M.(\omega) \right), \quad \mathbb{P}\text{-a.s.}, \]

where
\[ M_t = \int_0^t F(s, X_s) \, ds + \int_0^t G(s, X_s) \, dB_s. \]
**Definition 36.** Let \( F(\omega, t, x) := f(t, x), G(\omega, t, x) := g(t, x) \) and \( \xi(\omega) := x_0 \) (be independent of \( \omega \)). If there exist a stochastic basis \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t)_{t \geq 0}\), an \( \mathbb{R}^d \)-valued \( \mathcal{F}_t \)-Brownian motion \( \{B_t : t \geq 0\} \) and a pair \((X, K) : \Omega \times \mathbb{R}_+ \to \mathbb{R}_+ \times \mathbb{R}^d \) of p.m.c.s.p. such that

\[
(X(\omega), K(\omega)) = \mathcal{SP}(\phi^\omega(x_0, M(\omega))), \quad \mathbb{P}-a.s.,
\]

where

\[
M_t = \int_0^t f(s, X_s) \, ds + \int_0^t g(s, X_s) \, dB_s,
\]

then the collection \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t, X_t, K_t)_{t \geq 0}\) is called a weak solution of the stochastic Skorohod equation (40).

Since the stochastic process \( K \) is uniquely determined from \( (X, B) \) through equation (44-ff), we can also say that \( X \) is a strong solution (and respectively \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t, X_t)_{t \geq 0}\) is a weak solution).

We first give a uniqueness result for strong solutions.

**Proposition 37 (Pathwise uniqueness).** Let \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t)_{t \geq 0}\) be given and assumptions (9), (10) and (16) be satisfied. The functions \( F \) and \( G \) are such that assumptions (A1)–(A3) are satisfied. Then the stochastic Skorohod equation (40) has at most one strong solution.

**Proof.** Let \((X, K)\) and \((\hat{X}, \hat{K})\) be two solutions corresponding to \( \xi \) and respectively \( \hat{\xi} \). Since

\[
dK_t \in \delta^-\varphi(X_t)(dt) \quad \text{and} \quad d\hat{K}_t \in \delta^-\varphi(\hat{X}_t)(dt),
\]

by Lemma 17, for \( p \geq 1 \) and \( \lambda > 0 \)

\[
\|X_t - \hat{X}_t, (F(t, X_t) \, dt - dK_t) - (F(t, \hat{X}_t) \, dt - d\hat{K}_t)\|
\]

\[
\leq \left( \frac{1}{2} m_p + 9 p \right) \|G(t, X_t) - G(t, \hat{X}_t)\|^2 dt \leq |X_t - \hat{X}_t|^2 dV_t,
\]

where

\[
V_t = \int_0^t \left[ \mu(s) \, ds + \left( \frac{1}{2} m_p + 9 p \right) \dot{s}^2(s) \, ds + 2 \rho ds + \gamma d \hat{K} \hat{s} + \gamma d \hat{\xi} \hat{s} \right].
\]

Therefore, by Corollary 51 (from Appendix A), we get

\[
\mathbb{E} \left[ 1 \land \|e^{-V} (X - \hat{X})\|_T^p \right] \leq C_{p, \lambda} \mathbb{E} \left[ 1 \land |\xi - \hat{\xi}|^p \right],
\]

and the uniqueness follows. \( \square \)

Remark also that in the case of additive noise (i.e. \( G \) does not depend upon \( X \)) we have existence of a strong solution.
Lemma 38. Let \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, B_t)_{t \geq 0}\) be given and assumptions (9), (10), (16) and (17) be satisfied. The function \(F\) is such that assumptions \((A_1)-(A_3)\) are satisfied.

If

\[ \xi \in L^0(\Omega, \mathcal{F}_0, \mathbb{P}; \text{Dom}(\varphi)) \]

and \(M\) is a p.m.c.s.p. with \(M_0 = 0\), then there exists a unique pair \((X, K)\) of p.m.c.s.p., solution of the problem

\[ (X(\omega), K(\omega)) = \mathcal{S}P(\partial^{-\varphi}; \xi(\omega), M(\omega)), \mathbb{P}\text{-a.s.}, \]

i.e.

\[
\begin{aligned}
X_t(\omega) + K_t(\omega) &= \xi(\omega) + \int_0^t F(\omega, s, X_s(\omega)) ds + M_t(\omega), \quad t \geq 0, \\
\text{d}K_t(\omega) &\in \partial^{-\varphi}(X_t(\omega)) \,(dt), 
\end{aligned}
\]

\(\mathbb{P}\text{-a.s.}

Proof. Applying Corollary 34 to the approximating problem

\[
\begin{aligned}
X^n_t(\omega) + K^n_t(\omega) &= \xi(\omega) + \int_0^t F(\omega, s, X^n_{s-1/n}(\omega)) ds + M_t(\omega), \quad t \geq 0, \\
\text{d}K^n_t(\omega) &\in \partial^{-\varphi}(X^n_t(\omega)) \,(dt),
\end{aligned}
\]

we conclude that there exists a unique solution \((X^n, K^n)\) of p.m.c.s.p. The solution \((X, K)\) is obtained as the limit of the sequence \((X^n, K^n)\), exactly as in the proof of Proposition 30. \(\square\)

In order to study the general stochastic Skorohod equation (40) we shall consider only the case when \(F, G\) and \(\xi\) are independent of \(\omega\) and, to highlight this, the coefficients will be denoted by \(f\) and \(g\) respectively.

Let us consider equation

\[
\begin{aligned}
X_t + K_t &= x_0 + \int_0^t f(s, X_s) \, ds + \int_0^t g(s, X_s) \, dB_s, \quad t \geq 0, \\
\text{d}K_t(\omega) &\in \partial^{-\varphi}(X_t(\omega)) \,(dt), 
\end{aligned}
\]

(45)

where \(f : \mathbb{R}_+ \times \mathbb{R}^d \to \mathbb{R}^d\) and \(g : \mathbb{R}_+ \times \mathbb{R}^d \to \mathbb{R}^{d \times k}\).

We recall the definition of \(f^\#\), \(g^\#\) given as in (35).

Theorem 39. Let assumptions (9), (10), (16) and (17) be satisfied. The functions \(f\) and \(g\) are suppose to be \((B_1, \mathbb{R}^d)\)-Carathéodory functions satisfying moreover the boundedness conditions

Please cite this article in press as: R. Buckdahn et al., Stochastic variational inequalities on non-convex domains, J. Differential Equations (2015), http://dx.doi.org/10.1016/j.jde.2015.08.023
\[
\int_0^T \left[ |f^\#(s)|^2 + |g^\#(s)|^4 \right] ds < \infty, \forall T \geq 0.
\]

If \( x_0 \in \text{Dom}(\varphi) \) then equation (45) has a weak solution \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t, X_t, K_t, B_t)_{t \geq 0}\).

**Remark 40.** Usually, when \( G \) is Lipschitz, a fixed point argument is used (based on Banach contraction theorem). But, in our case this argument doesn’t work even for the drift part \( F \equiv 0 \), as it can be seen from inequality (22), we have different order of the estimates in the left and in the right side of the inequality.

**Proof.**

**Step 1. Approximating sequence.**

Let \((\Omega, \mathcal{F}, \mathbb{P}, \mathcal{F}_t^B, B_t)_{t \geq 0}\) be a stochastic basis. Applying Lemma 38, we deduce that there exists a unique pair \((X^n, K^n) : \Omega \times \mathbb{R}_+ \to \mathbb{R}^d \times \mathbb{R}^d\) of \(\mathcal{F}_t^B\)-p.m.c.s.p. such that

\[
\begin{aligned}
X^n_t + K^n_t &= x_0 + \int_0^t f(s, X^n_{s-1/n}) ds + \int_0^t g(s, X^n_{s-1/n}) dB_s, \quad t \geq 0, \\
dK^n_t(\omega) &\in \partial^- \varphi \left( X^n_t(\omega) \right) (dt).
\end{aligned}
\]

Denote

\[
M^n_t := \int_0^t f\left(s, X^n_{s-1/n}\right) ds + \int_0^t g\left(s, X^n_{s-1/n}\right) dB_s.
\]

Since

\[
\mathbb{E}\left[ \sup_{0 \leq \theta \leq \epsilon} \left| M^n_{t+\theta} - M^n_t \right| ^4 \right] \leq C \left[ \left( \int_t^{t+\epsilon} |f^\#(s)| ds \right)^4 + \left( \int_t^{t+\epsilon} |g^\#(s)|^2 ds \right)^2 \right],
\]

\[
\leq C \left( \sup_{t \in [0, T]} \left( \int_t^{t+\epsilon} |f^\#(s)|^2 ds \right) ^2 + \sup_{t \in [0, T]} \int_t^{t+\epsilon} |g^\#(s)|^4 ds \right)
\]

using Proposition 46, we deduce that the family of laws of \(\{M^n : n \geq 1\}\) is tight on \(\mathbb{R}_+; \mathbb{R}^d\).

Therefore by Theorem 45 for all \(T \geq 0\)

\[
\lim_{N \to \infty} \sup_{n \geq 1} \mathbb{P}\left( \|M^n\|_T \geq N \right) = 0,
\]

and, for all \(a > 0\) and \(T > 0\),

Please cite this article in press as: R. Buckdahn et al., Stochastic variational inequalities on non-convex domains, J. Differential Equations (2015), http://dx.doi.org/10.1016/j.jde.2015.08.023
\[ \lim_{\epsilon \searrow 0} \sup_{n \geq 1} \mathbb{P}(\{ m_{M^n} (\epsilon) \geq a \}) = 0. \] (47)

Recalling the definition
\[ \mu_{M^n} = \epsilon + m_{M^n} (\epsilon), \]
where \( m \) is the modulus of continuity, we see that we can replace in (47) \( m_{M^n} \) by \( \mu_{M^n} \).

**Step 2. Tightness.**

Let \( T \geq 0 \) be arbitrary. We now show that the family of laws of the random variables \( U^n = (X^n, K^n, \uparrow K^n \downarrow) \) is tight on \( C([0, T]; \mathbb{R}^{2d+1}) \).

From (21-c) we deduce that
\[ m_{U^n} (\epsilon) \leq G (M^n) \sqrt{\mu_{M^n} (\epsilon)}, \text{ a.s.,} \]
where \( G : C([0, T]; \mathbb{R}^d) \to \mathbb{R}_+ \) and
\[ G(x) := C_{T,x} = \exp \left[ C(1 + T + \| x \|_T + B_x) \right], \]
\[ B_x := \frac{1}{\mu_x^{-1}} \left( \epsilon^2 e^{-C(1+\| x \|_T)} \right). \]

From (20) we see that \( G \) is bounded on compact subset of \( C([0, T]; \mathbb{R}^d) \) and therefore by Proposition 47, \( \{ U^n; n \in \mathbb{N}^* \} \) is tight on \( C([0, T]; \mathbb{R}^{2d}) \).

Using the Prohorov theorem we see that there exists a subsequence (still denoted with \( n \)) such that
\[ (X^n, K^n, \uparrow K^n \downarrow, B) \to (X, K, V, B) \quad \text{in law, as } n \to \infty \]
on \( C([0, T]; \mathbb{R}^{2d+1+k}) \) and applying the Skorohod theorem, we can choose a probability space \( (\Omega, \mathcal{F}, \mathbb{P}) \) and some random quadruples \( (\tilde{X}^n, \tilde{K}^n, \tilde{V}^n, \tilde{B}^n), (\tilde{X}, \tilde{K}, \tilde{V}, \tilde{B}) \) defined on \( (\Omega, \mathcal{F}, \mathbb{P}) \) such that
\[ \mathcal{L}(\tilde{X}^n, \tilde{K}^n, \tilde{V}^n, \tilde{B}^n) = \mathcal{L}(X^n, K^n, \uparrow K^n \downarrow, B^n) \]
\[ \mathcal{L}(\tilde{X}, \tilde{K}, \tilde{V}, \tilde{B}) = \mathcal{L}(X, K, V, B) \]
and
\[ (\tilde{X}^n, \tilde{K}^n, \tilde{V}^n, \tilde{B}^n) \xrightarrow{\mathbb{P}-\text{a.s.}} (\tilde{X}, \tilde{K}, \tilde{V}, \tilde{B}), \text{ as } n \to \infty, \text{ in } C([0, T]; \mathbb{R}^{2d+1+k}). \]

From Proposition 49 we deduce that \( (\tilde{B}^n, \{ F_t^{\tilde{X}^n, \tilde{K}^n, \tilde{V}^n, \tilde{B}^n} \}), n \geq 1 \), and \( (\tilde{B}, \{ F_t^{\tilde{X}, \tilde{K}, \tilde{V}, \tilde{B}} \}) \) are Brownian motions.

**Step 3. Passing to the limit.**
Since we also have \((X^n, K^n, \bar{\downarrow} K^n \downarrow B) \to (\bar{X}, \bar{K}, \bar{V}, \bar{B})\), in law, then by Corollary 43 we deduce that for all \(0 \leq s \leq t\), \(\bar{V}\)-a.s.

\[
\begin{align*}
\bar{X}_0 &= x_0, \quad \bar{K}_0 = 0, \quad \bar{X}_t \in \text{Dom}(\varphi), \\
\underline{\bar{K}}_r \downarrow - \bar{K}_r \downarrow s &\leq \bar{V}_t - \bar{V}_s \quad \text{and} \quad 0 = \bar{V}_0 \leq \bar{V}_s \leq \bar{V}_t
\end{align*}
\]  
(48)

Moreover, since for all \(0 \leq s < t\), \(n \in \mathbb{N}^*\)

\[
\int_s^t \varphi(X^n_r) \, dr \leq \int_s^t \varphi(y(r)) \, dr - \int_s^t \{ y(r) - X^n_r \, dK^n_r \} \\
+ \int_s^t |y(r) - X^n_r|^2 (\rho \, dr + \gamma \, d\underline{\bar{K}}_r \downarrow), \quad \text{a.s.,}
\]

then by Corollary 44 we infer that

\[
\int_s^t \varphi(\bar{X}_r) \, dr \leq \int_s^t \varphi(y(r)) \, dr - \int_s^t \{ y(r) - \bar{X}_r \, d\bar{K}_r \} \\
+ \int_s^t |y(r) - \bar{X}_r|^2 (\rho \, dr + \gamma \, d\bar{V}_r). \quad (49)
\]

Hence, based on (48) and (52) and Lemma 16 we have

\[d\bar{K}_r \in \partial^+ \varphi(\bar{X}_r)(dr).\]

Let

\[S_t(Y, B) := x_0 + \int_0^t f(s, Y_s) \, ds + \int_0^t g(s, Y_s) \, dB_s, \quad t \geq 0.\]

By Proposition 48 it follows

\[\mathcal{L}(\bar{X}^n, \bar{K}^n, \bar{V}^n, \bar{B}^n, S_t(\bar{X}^n, \bar{B}^n)) = \mathcal{L}(X^n, K^n, \underline{\bar{K}}_r \downarrow, B^n, S_t(X^n, B^n))\]

Since for every \(t \geq 0\),

\[X^n_t + K^n_t - S_t(X^n, B^n) = 0, \quad \text{a.s.,}\]

then by Corollary 43 we have

\[\bar{X}_t^n + \bar{K}_t^n - S_t(\bar{X}_t^n, \bar{B}_t^n) = 0, \quad \text{a.s.,}\]

and consequently, letting \(n \to \infty\),

Please cite this article in press as: R. Buckdahn et al., Stochastic variational inequalities on non-convex domains, J. Differential Equations (2015), http://dx.doi.org/10.1016/j.jde.2015.08.023
\[ \bar{X}_t + \bar{K}_t - S_t(\bar{X}, \bar{B}) = 0, \text{ a.s.} \]

Hence we obtain that, \( \mathbb{P} \)-a.s.,

\[ \bar{X}_t + \bar{K}_t = x_0 + \int_0^t f(s, \bar{X}_s) \, ds + \int_0^t g(s, \bar{X}_s) \, d\bar{B}_s, \quad \forall \ t \in [0, T], \]

and consequently \( (\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}}, \tilde{F}_t, \tilde{\bar{X}}, \tilde{\bar{K}}, \tilde{\bar{B}})_{t \geq 0} \) is a weak solution. \( \square \)

Since the stochastic process \( K \) is uniquely determined by \( (X, B) \) via equation (45), then a weak solution for the stochastic differential equation is a sextuplet \( (\tilde{\Omega}, \tilde{\mathcal{F}}, \tilde{\mathbb{P}}, \{\tilde{F}_t\}_{t \geq 0}, X, B) \). We know that weak existence and pathwise uniqueness implies strong existence (see Theorem 3.55 in [31] or Theorem 1.1 in [23]). Hence we deduce from Theorem 39 and Proposition 37:

**Theorem 41.** Let assumptions (9), (10), (16) and (17) be satisfied. The functions \( f \) and \( g \) are suppose to be \( (\mathcal{B}_1, \mathbb{R}^d) \)-Carathéodory functions satisfying moreover assumption (A3) and boundedness conditions

\[ \int_0^T \left[ |f^\#(s)|^2 + |g^\#(s)|^4 \right] \, ds < \infty, \quad \forall T \geq 0. \]

If \( x_0 \in \text{Dom}(\psi) \) then equation (45) has a unique strong solution \( (X_t, K_t)_{t \geq 0} \).

**Appendix A**

**A.1. Applications of Fatou’s Lemma**

The next result is a well known consequence of weak convergence of probability measures (for its proof see, e.g. [31, Proposition 1.22]).

**Proposition 42.** Let \( (\mathcal{X}, \rho) \) be a separable metric space. Let \( \varphi: \mathcal{X} \to (-\infty, \infty] \) be a lower semicontinuous function. If \( X \) and \( X_n \) are \( \mathcal{X} \)-valued random variables, for \( n \in \mathbb{N}^* \), such that

(i) \( X_n \xrightarrow{\text{law}} X \) as \( n \to \infty \),

and there exists a continuous function \( \alpha: \mathcal{X} \to \mathbb{R} \) such that

(ii) \( \alpha(x) \leq \varphi(x), \quad \forall x \in \mathcal{X} \),

(iii) \( \{\alpha(X_n): n \in \mathbb{N}^*\} \) is a uniformly integrable family,
then the expectations $\mathbb{E} \varphi (X) \text{ and } \mathbb{E} \varphi (X_n)$ exist for all $n \in \mathbb{N}$, and

$$-\infty < \mathbb{E} \varphi (X) \leq \liminf_{n \to +\infty} \mathbb{E} \varphi (X_n).$$

For $0 \leq s < t \leq T$, we denote by $\uparrow X_{[s,t]}$ (similar to (7)) the total variation of $X$ on $[s,t]$, that is

$$\uparrow X_{[s,t]}(\omega) = \sup \left\{ \sum_{i=0}^{n-1} |X_{t_{i+1}}(\omega) - X_{t_i}(\omega)| : n \in \mathbb{N}^*, s = t_0 < t_1 < \ldots < t_n = t \right\}$$

We also use $\uparrow X_T := \uparrow X_{[0,T]}$.

Applying successively Proposition 42 for

$$\varphi (x) = d_F (x(t)),$$

$$\varphi (x, y) = \left( \sum_{i=0}^{N-1} |x(t_{i+1}) - x(t_i)| - g(y) \right)^+,$$

where $s = t_0 < t_1 < \ldots < t_N = t$ is an arbitrary partition of $[s,t]$, and respectively

$$\varphi (x) = (x(s) - x(t))^+,$$

we get the next result:

**Corollary 43.** Let $s$, $t$ be arbitrary fixed such that $0 \leq s \leq t \leq T$. If $g : C ([0, T]; \mathbb{R}^d) \to \mathbb{R}_+$ is a continuous function and $X$, $V$, $X^n$, $V^n$, $n \in \mathbb{N}^*$, are random variables with values in $C ([0, T]; \mathbb{R}^d)$, such that

$$(X^n, V^n) \xrightarrow{\text{law}} (X, V), \text{ as } n \to \infty,$$

then the following implications hold true:

(a) If $X^n_{[t]} \in F$ a.s., then $X_t \in F$, a.s., whenever $F$ is closed subset of $\mathbb{R}^d$;

(b) If $\uparrow X^n_{[s,t]} \leq g (V^n)$ a.s., then $\uparrow X_{[s,t]} \leq g (V)$, a.s.;

(c) If $d = 1$ and $X^n_s \leq X^n_{t}$ a.s., then $X_s \leq X_t$, a.s.

Now let us consider the partition

$$\Delta_N : s = r_0 < r_1 < \ldots < r_N = t, \quad r_{i+1} - r_i = \frac{t-s}{N}$$

and the function $g : C ([0, T]; \mathbb{R}^d) \to [0, 1]$, defined by

$$g (x, k, v) : = \left( \sum_{i=0}^{N-1} |k(r_{i+1}) - k(r_i)| - v(t) + v(s) \right)^+ \wedge 1$$

$$\left[ \int_s^t \varphi (x (r)) dr - \sum_{i=0}^{N-1} (x (r_i) , k (r_{i+1}) - k (r_i)) - m_N (1/N) (v(t) - v(s)) \right]^+ \wedge 1.$$
Applying again the generalization of the Fatou’s Lemma (Proposition 42), it can be proved:

**Corollary 44.** Let \((X, K, V), (X^n, K^n, V^n), n \in \mathbb{N},\) be \(C([0, T]; \mathbb{R}^d)^2 \times C([0, T]; \mathbb{R})\)-valued random variables, such that

\[
(X^n, K^n, V^n) \xrightarrow{\text{law}} (X, K, V)
\]

and for all \(0 \leq s < t,\) and \(n \in \mathbb{N}^*,\)

\[
\uparrow K^n\downarrow_t - \uparrow K^n\downarrow_s \leq V^n_t - V^n_s \quad \text{a.s.}
\]

If \(\varphi : \mathbb{R}^d \to (-\infty, +\infty]\) is a lower semicontinuous function and

\[
\int_s^t \varphi(X^n_r) dr \leq \int_s^t \langle X^n_r, dK^n_r \rangle, \text{a.s. for all } n \in \mathbb{N}^*,
\]

then

\[
\uparrow K\downarrow_t - \uparrow K\downarrow_s \leq V_t - V_s, \text{ a.s.}
\]

and

\[
\int_s^t \varphi(X_r) dr \leq \int_s^t \langle X_r, dK_r \rangle, \text{ a.s.}
\]

**A.2. Complements on tightness**

If \(\{X^n_t : t \geq 0\}, n \in \mathbb{N}^*,\) is a family of continuous stochastic processes then the following result is a consequence of the Arzelà–Ascoli theorem (see, e.g., Theorem 7.3 in [6]).

We recall the notations:

\[
\|X^n\|_T := \sup \{ \|X^n_t\| : t \in [0, T] \},
\]

\[
m_{X^n}(\varepsilon; [0, T]) := \sup \{ \|X^n_t - X^n_s\| : t, s \in [0, T], |t - s| \leq \varepsilon \}.
\]

**Theorem 45.** The family \(\{X^n : n \in \mathbb{N}^*\}\) is tight in \(C(\mathbb{R}^+; \mathbb{R}^d)\) if and only if, for every \(T \geq 0,\)

\[
(j) \quad \lim_{N \nearrow \infty} \sup_{n \geq 1} \mathbb{P}^{(n)}(\|X^n_0\| \geq N) = 0,
\]

\[
(jj) \lim_{\varepsilon \searrow 0} \sup_{n \geq 1} \mathbb{P}^{(n)}(m_{X^n}(\varepsilon; [0, T]) \geq a) = 0, \quad \forall a > 0.
\]

Moreover, tightness yields that for all \(T > 0\)

\[
\lim_{N \nearrow \infty} \sup_{n \geq 1} \mathbb{P}^{(n)}(\|X^n\|_T \geq N) = 0.
\]
Without using the above theorem, it can be proved the following criterion for tightness which is well adapted to our needs. The proof can be found in E. Pardoux and A. Răşcanu [31] (Proposition 1.53) and we will give the sketch of the proof.

**Proposition 46.** Let \( \{X^n_t : t \geq 0\} \), \( n \in \mathbb{N}^* \), be a family of \( \mathbb{R}^d \)-valued continuous stochastic processes defined on probability space \((\Omega, \mathcal{F}, \mathbb{P})\). Suppose that for every \( T \geq 0 \), there exist \( \alpha > 0 \) and \( b \in C (\mathbb{R}_+) \) with \( b(0) = 0 \), such that

\[
\begin{align*}
(j) \quad \lim_{N \to \infty} \sup_{n \in \mathbb{N}^*} \mathbb{P}(\{|X^n_0| \geq N\}) &= 0, \\
(ii) \quad \mathbb{E} \left[ \max_{0 \leq s \leq t} |X^n_{t+s} - X^n_t|^\alpha \right] &\leq \epsilon \cdot b(\epsilon), \quad \forall \epsilon > 0, \ n \geq 1, \ t \in [0, T].
\end{align*}
\]

Then the family \( \{X^n : n \in \mathbb{N}^*\} \) is tight in \( C(\mathbb{R}_+; \mathbb{R}^d) \).

**Proof.** We fix \( \epsilon, T > 0 \). From \((j)\), there exists \( M = M_\epsilon \geq 1 \) such that

\[
\sup_{n \in \mathbb{N}^*} \mathbb{P}(\{|X^n_0| \geq M\}) < \frac{\epsilon}{2}.
\]

Let \( \gamma_k = \frac{1}{2(k-1)/\alpha} \) and \( \epsilon_k \searrow 0 \) be such that \( b(\epsilon_k) \leq \frac{\epsilon}{4k^\alpha T} \). Let \( N_k = \left[ \frac{T}{\epsilon_k} \right] \) and \( t_i = \frac{(i-1)T}{N_k} \).

Applying Theorem Arzelá–Ascoli we see that the set

\[
K_\epsilon = \left\{ z \in C([0, T]; \mathbb{R}^d) : |z(0)| \leq M, \sup_{0 \leq s \leq \epsilon_k} |z(t_i + s) - z(t_i)| \leq \gamma_k, \forall k \in \mathbb{N}^* \right\}
\]

is compact in \( C([0, T]; \mathbb{R}^d) \).

From Markov’s inequality and \((ij)\)

\[
\mathbb{P}(X^n \notin K_\epsilon) \leq \mathbb{P}(\{|X^n_0| > M\}) + \sum_{k \in \mathbb{N}^*} \sum_{i=1}^{N_k} \mathbb{P}(\sup_{0 \leq s \leq \epsilon_k} |X^n_{t_i+s} - X^n_{t_i}| > \gamma_k)
\]

\[
\leq \frac{\epsilon}{2} + \sum_{k \in \mathbb{N}^*} \frac{\epsilon_k \times b(\epsilon_k)}{\gamma_k^\alpha} \leq \frac{\epsilon}{2} + \sum_{k \in \mathbb{N}^*} \frac{N_k \times \epsilon_k \times b(\epsilon_k)}{\gamma_k^\alpha} \leq \epsilon.
\]

The proof is complete now. \( \square \)

**Proposition 47.** Let \( g : \mathbb{R}_+ \to \mathbb{R}_+ \) be a continuous function satisfying \( g(0) = 0 \) and \( G : C(\mathbb{R}_+; \mathbb{R}^d) \to \mathbb{R}_+ \) be a mapping which is bounded on compact subsets of \( C(\mathbb{R}_+; \mathbb{R}^d) \). Let \( X^n, Y^n, n \in \mathbb{N}^* \), be random variables with values in \( C(\mathbb{R}_+; \mathbb{R}^d) \). If \( \{Y^n : n \in \mathbb{N}^*\} \) is tight and for all \( n \in \mathbb{N}^* \)

Please cite this article in press as: R. Buckdahn et al., Stochastic variational inequalities on non-convex domains, J. Differential Equations (2015), http://dx.doi.org/10.1016/j.jde.2015.08.023
\[(i) \quad |X_0^n| \leq G(Y^n), \text{ a.s.}\]
\[(ii) \quad m_{X^n}(\varepsilon; [0, T]) \leq G(Y^n) g(m_{Y^n}(\varepsilon; [0, T])), \text{ a.s., } \forall \varepsilon, T > 0,\]

then \(\{X^n : n \in \mathbb{N}^*\}\) is tight.

**Proof.** Let \(\delta > 0\) be arbitrary. Then there exists a compact set \(K_\delta \subset C([0, \infty); \mathbb{R}^d)\) such that for all \(n \in \mathbb{N}^*\)
\[
\mathbb{P}(Y^n \notin K_\delta) < \delta.
\]
Define \(N_\delta = \sup_{x \in K_\delta} G(x).\) Then
\[
\mathbb{P}(|X^n_0| > N_\delta) < \delta.
\]
Let \(a > 0\) be arbitrary. There exists \(\varepsilon_0 > 0\) such that
\[
\sup_{x \in K_\delta} \frac{g(m_x(\varepsilon; [0, T]))}{N_\delta} \leq \frac{a}{N_\delta}, \quad \forall 0 < \varepsilon < \varepsilon_0.
\]
Consequently for all \(n \in \mathbb{N}^*\),
\[
\mathbb{P}(m_{X^n}(\varepsilon; [0, T]) \geq a) \leq \mathbb{P}\left[\frac{g(m_{Y^n}(\varepsilon; [0, T]))}{N_\delta} \geq \frac{a}{N_\delta}, \quad Y^n \in K_\delta\right] + \mathbb{P}(Y^n \notin K_\delta) \leq \delta
\]
and the result follows. \(\square\)

**A.3. Itô’s stochastic integral**

In this subsection we consider \(\{B_t : t \geq 0\}\) to be a \(k\)-dimensional Brownian motion on a stochastic basis (which is supposed to be complete and right-continuous) \((\Omega, \mathcal{F}, \mathbb{P}, \{\mathcal{F}_t\}_{t \geq 0})\).

Let \(S_d[0\,T]\) be the space of p.m.c.s.p. \(X : \Omega \times [0, T] \to \mathbb{R}^d\) and \(\Lambda_d(0, T)\) the space of p.m.c.s.p. \(X : \Omega \times [0, T] \to \mathbb{R}^d\) such that
\[
\int_0^T |X_t|^2 \, dt < \infty, \quad \mathbb{P}\text{-a.s.}
\]
Write \(S_d\) (and \(\Lambda_d\)) for space of p.m.c.s.p. \(X : \Omega \times [0, T] \to \mathbb{R}^d\) such that the restriction of \(X\) to \([0, T]\) belongs to \(S_d\) (respectively to \(\Lambda_d\)).

If \(X \in S_{d \times k}\) and \(B\) is an \(\mathbb{R}^k\)-Brownian motion, then the stochastic process \(\{(X_t, B_t) : t \geq 0\}\) can be seen as a random variable with values in the space \(C(\mathbb{R}^+; \mathbb{R}^{d \times k}) \times C(\mathbb{R}^+, \mathbb{R}^k)\). The law of this random variable will be denoted \(\mathcal{L}(X, B)\).

**Proposition 48. (See Corollary 2.13 in [31].)** Let \(X, \hat{X} \in S_d[0, T]\), \(B, \hat{B}\) be two \(\mathbb{R}^k\)-Brownian motions and \(g : \mathbb{R}^+ \times \mathbb{R}^d \to \mathbb{R}^{d \times k}\) be a function such that

Please cite this article in press as: R. Buckdahn et al., Stochastic variational inequalities on non-convex domains, J. Differential Equations (2015), http://dx.doi.org/10.1016/j.jde.2015.08.023
If $g(\cdot, y)$ is measurable $\forall y \in \mathbb{R}^d$, $y \mapsto g(t, y)$ is continuous $dt$-a.e.

If $\mathcal{L}(X, B) = \mathcal{L}(\tilde{X}, \tilde{B})$ on $C(\mathbb{R}^+, \mathbb{R}^{d+k})$, then

$$\mathcal{L}(X, B, \int_0^t g(s, X_s) dB_s) = \mathcal{L}(\tilde{X}, \tilde{B}, \int_0^t g(s, \tilde{X}_s) d\tilde{B}_s)$$
on $C(\mathbb{R}^+, \mathbb{R}^{d+k+d})$.

We present now a continuity property of the mapping

$$(X, B) \mapsto \int_0^T X_s dB_s.$$

Given $B: \Omega \times \mathbb{R}^+ \rightarrow \mathbb{R}^k$ and $X: \Omega \times \mathbb{R}^+ \rightarrow \mathbb{R}^d \times k$ be two stochastic processes, let $\mathcal{F}^B_X$ be the natural filtration generated jointly by $B$ and $X$.

For the proof of the next proposition see Proposition 2.4 in [9] or Proposition 2.14 in [31].

**Proposition 49.** Let $B, B^n, \tilde{B}^n: \Omega \times \mathbb{R}^+ \rightarrow \mathbb{R}^k$ and $X, X^n, \tilde{X}^n: \Omega \times \mathbb{R}^+ \rightarrow \mathbb{R}^d \times k$ be continuous stochastic processes such that

(i) $\tilde{B}^n$ is $\mathcal{F}^X^n$-Brownian motion $\forall n \geq 1$;
(ii) $\mathcal{L}(\tilde{B}^n, \tilde{X}^n) = \mathcal{L}(B^n, X^n)$ on $C(\mathbb{R}^+, \mathbb{R}^k \times \mathbb{R}^d)$, for all $n \geq 1$;
(iii) $\int_0^T |X^n_s - X_s|^2 ds + \sup_{t \in [0, T]} |B^n_t - B_t| \rightarrow 0$, in probability, as $n \rightarrow \infty$, for all $T > 0$.

Then $(B^n, \mathcal{F}^B_X^n), n \geq 1$, and $(B, \mathcal{F}^B_X)$ are Brownian motions and as $n \rightarrow \infty$

$$\sup_{t \in [0, T]} \left| \int_0^t X^n_s dB^n_s - \int_0^t X_s dB_s \right| \rightarrow 0 \quad \text{in probability.}$$

(A.4. A forward stochastic inequality)

Let $X, \tilde{X} \in S_d$ be two semimartingales defined by

$$X_t = X_0 + K_t + \int_0^t G_s dB_s, \quad t \geq 0, \quad \tilde{X}_t = \tilde{X}_0 + \tilde{K}_t + \int_0^t \tilde{G}_s dB_s, \quad t \geq 0,$$

where
\( K, \hat{K} \in S_d; \)
\( K, (\omega), \hat{K}, (\omega) \in BV_{loc}(\mathbb{R}^+; \mathbb{R}^d), K_0(\omega) = \hat{K}_0(\omega) = 0, \mathbb{P}\text{-a.s.}; \)
\( G, \hat{G} \in \Lambda_{d \times k}. \)

Assume that there exist \( p \geq 1 \) and \( \lambda \geq 0 \) and \( V \) a bounded variation p.m.c.s.p., with \( V_0 = 0 \), such that, as measures on \( \mathbb{R}^+ \),

\[ |X_t - \hat{X}_t, dK_t - d\hat{K}_t| + \left( \frac{1}{2} m_p + 9 p \lambda \right) |G_t - \hat{G}_t|^2 dt \leq |X_t - \hat{X}_t|^2 dV_t. \quad (52) \]

**Theorem 50.** (See Corollary 6.74 in [31].) Let \( p \geq 1 \). If the assumption (52) is satisfied with \( \lambda > 1 \), then there exists a positive constant \( C_{p,\lambda} \) such that for all \( \delta \geq 0 \), \( 0 \leq t \leq s \):

\[
\mathbb{E}^{\mathcal{F}_t} \left[ \frac{|e^{-V(X - \hat{X})}|_{(t,s)}}{|1 + \delta|e^{-V(X - \hat{X})}|_{(t,s)}^2} \right]^{p/2} \leq C_{p,\lambda} \frac{e^{-pV_t |X_t - \hat{X}_t|^p}}{(1 + \delta^2 e^{-2V_t |X_t - \hat{X}_t|^2})^{p/2}}, \quad \mathbb{P}\text{-a.s.}
\]

In particular for \( \delta = 0 \)

\[
\mathbb{E}^{\mathcal{F}_t} \left[ |e^{-V(X - \hat{X})}|_{(t,s)}^p \right] \leq C_{p,\lambda} e^{-pV_t |X_t - \hat{X}_t|^p}, \quad \mathbb{P}\text{-a.s.,}
\]

for all \( 0 \leq t \leq s \).

As a consequence of the above theorem, since

\[
\frac{1}{2} (1 \wedge r) \leq \frac{r}{(1 + r^2)^{1/2}} \leq 1 \wedge r, \quad \forall r \geq 0,
\]

we obtain:

**Corollary 51.** If assumption (52) is satisfied with \( \lambda > 1 \) and \( p \geq 1 \), then there exists a positive constant \( C_{p,\lambda} \) depending only on \( (p, \lambda) \) such that \( \mathbb{P}\text{-a.s.} \)

\[
\mathbb{E}^{\mathcal{F}_t} \left[ 1 \wedge |e^{-V(X - \hat{X})}|_{(t,s)}^p \right] \leq C_{p,\lambda} \left[ 1 \wedge |e^{-V_t(X_t - \hat{X}_t)|^p} \right],
\]

for all \( 0 \leq t \leq s \).
