Abstract. We introduce here a new finite volume scheme which was developed for the discretization of anisotropic diffusion problems; the originality of this scheme lies in the fact that we are able to prove its convergence under very weak assumptions on the discretization mesh. © 2007 Académie des sciences/Éditions scientifiques et médicales Elsevier SAS

Un nouveau schéma volumes finis pour les problèmes de diffusion anisotrope : analyse de convergence

Résumé. On introduit ici un nouveau schéma volumes finis, construit pour la discrétisation de problèmes de diffusion anisotrope sur des maillages généraux ; l'originalité de ce travail réside dans sa preuve de convergence, qui ne nécessite que des hypothèses faibles sur le maillage. © 2007 Académie des sciences/Éditions scientifiques et médicales Elsevier SAS

1. Introduction

The scope of this work is the discretization by a finite volume method of anisotropic diffusion problems on general meshes. Let Ω be a polygonal (or polyhedral) open subset of \mathbb{R}^d ($d = 2$ or 3); let $\mathcal{M}_d(\mathbb{R})$ be the set of $d \times d$ symmetric matrices. We consider the following elliptic conservation equation:

$$-\operatorname{div}(\Lambda \nabla u) = f \text{ in } \Omega, \quad (1)$$

with boundary condition

$$u = 0 \text{ on } \partial\Omega \quad (2)$$

with the following hypotheses on the data:

$$\Lambda \text{ is a measurable function from } \Omega \text{ to } \mathcal{M}_d(\mathbb{R}), \text{ and there exist } \underline{\lambda} \text{ and } \bar{\lambda} \text{ such that } 0 < \underline{\lambda} \leq \bar{\lambda} \text{ and } \operatorname{Sp}(\Lambda(x)) \subset [\underline{\lambda}, \bar{\lambda}] \text{ for a.e. } x \in \Omega. \text{ The function } f \text{ is such that } f \in L^2(\Omega). \quad (3)$$

In (4), $\text{Sp}(B)$ denotes for all $B \in \mathcal{M}_d(\mathbb{R})$ the set of the eigenvalues of B . We consider the following weak formulation of problem (2):

$$\begin{cases} u \in H_0^1(\Omega), \\ \int_{\Omega} \Lambda(x) \nabla u(x) \cdot \nabla v(x) dx = \int_{\Omega} f(x) v(x) dx, \quad \forall v \in H_0^1(\Omega). \end{cases} \quad (4)$$

2. Discrete functional tools

A finite volume discretization of Ω is a triplet $\mathcal{D} = (\mathcal{M}, \mathcal{E}, \mathcal{P})$, where:

- \mathcal{M} is a finite family of non empty connex open disjoint subsets of Ω (the “control volumes”) such that $\overline{\Omega} = \bigcup_{K \in \mathcal{M}} \overline{K}$. For any $K \in \mathcal{M}$, let $\partial K = \overline{K} \setminus K$ be the boundary of K and $m_K > 0$ denote the measure of K .
- \mathcal{E} is a finite family of disjoint subsets of $\overline{\Omega}$ (the “edges” of the mesh), such that, for all $\sigma \in \mathcal{E}$, σ is a non empty closed subset of a hyperplane of \mathbb{R}^d , which has a measure $m_{\sigma} > 0$ for the $(d-1)$ -dimensional measure of σ . We assume that, for all $K \in \mathcal{M}$, there exists a subset \mathcal{E}_K of \mathcal{E} such that $\partial K = \bigcup_{\sigma \in \mathcal{E}_K} \sigma$. We then denote by $\mathcal{M}_{\sigma} = \{K \in \mathcal{M}, \sigma \in \mathcal{E}_K\}$. We then assume that, for all $\sigma \in \mathcal{E}$, either \mathcal{M}_{σ} has exactly one element and then $\sigma \subset \partial\Omega$ (boundary edge) or \mathcal{M}_{σ} has exactly two elements (interior edge). For all $\sigma \in \mathcal{E}$, we denote by x_{σ} the barycenter of σ .
- \mathcal{P} is a family of points of Ω indexed by \mathcal{M} , denoted by $\mathcal{P} = (x_K)_{K \in \mathcal{M}}$, such that $x_K \in K$ and K is star-shaped with respect to x_K .

The following notations are used. The size of the discretization is defined by: $h_{\mathcal{D}} = \sup\{\text{diam}(K), K \in \mathcal{M}\}$. For all $K \in \mathcal{M}$ and $\sigma \in \mathcal{E}_K$, we denote for a.e. $x \in \sigma$ by $\mathbf{n}_{K,\sigma}$ the unit vector normal to σ outward to K . We denote by $d_{K,\sigma}$ the Euclidean distance between x_K and σ . The set of interior (resp. boundary) edges is denoted by \mathcal{E}_{int} (resp. \mathcal{E}_{ext}), that is $\mathcal{E}_{\text{int}} = \{\sigma \in \mathcal{E}; \sigma \not\subset \partial\Omega\}$ (resp. $\mathcal{E}_{\text{ext}} = \{\sigma \in \mathcal{E}; \sigma \subset \partial\Omega\}$). The regularity of the mesh is measured through the parameter $\theta_{\mathcal{D}} = \min \left\{ \frac{\min(d_{K,\sigma}, d_{L,\sigma})}{\max(d_{K,\sigma}, d_{L,\sigma})}, \sigma \in \mathcal{E}_{\text{int}}, \mathcal{M}_{\sigma} = \{K, L\} \right\}$.

A family \mathcal{F} of discretizations is regular if there exists $\theta > 0$ such that for any $\mathcal{D} \in \mathcal{F}$, $\theta_{\mathcal{D}} \geq \theta$.

Let $X_{\mathcal{D}} = \mathbb{R}^{\mathcal{M}} \times \mathbb{R}^{\mathcal{E}}$ be the set of all $u := ((u_K)_{K \in \mathcal{M}}, (u_{\sigma})_{\sigma \in \mathcal{E}})$, and let $X_{\mathcal{D},0} \subset X_{\mathcal{D}}$ be defined as the set of all $u \in X_{\mathcal{D}}$ such that $u_{\sigma} = 0$ for all $\sigma \in \mathcal{E}_{\text{ext}}$. The space $X_{\mathcal{D},0}$ is equipped with a Euclidean structure, defined by the following inner product:

$$\forall (v, w) \in (X_{\mathcal{D},0})^2, [v, w]_{\mathcal{D}} = \sum_{K \in \mathcal{M}} \sum_{\sigma \in \mathcal{E}_K} \frac{m_{\sigma}}{d_{K,\sigma}} (v_{\sigma} - v_K)(w_{\sigma} - w_K). \quad (5)$$

and the associated norm: $\|u\|_{1,\mathcal{D}} = ([u, u]_{\mathcal{D}})^{1/2}$. Let $H_{\mathcal{M}}(\Omega) \subset L^2(\Omega)$ be the set of piecewise constant functions on the control volumes on the mesh \mathcal{M} which is equipped with the following inner norm: $\|u\|_{1,\mathcal{M}} = \inf\{\|v\|_{1,\mathcal{D}}, v \in X_{\mathcal{D},0}, P_{\mathcal{M}}v = u\}$, where for all $u \in X_{\mathcal{D}}$, we denote by $P_{\mathcal{M}}u \in H_{\mathcal{M}}(\Omega)$ the element defined by the values $(u_K)_{K \in \mathcal{M}}$ (we then easily see that this definition of $\|\cdot\|_{1,\mathcal{M}}$ coincides with that given in [1] in the case where we set $d_{KL} = d_{K,\sigma} + d_{L,\sigma}$ for all $\sigma \in \mathcal{E}_{\text{int}}$ with $\mathcal{M}_{\sigma} = \{K, L\}$). For all $\varphi \in C(\Omega, \mathbb{R})$, we denote by $P_{\mathcal{D}}(\varphi)$ the element of $X_{\mathcal{D}}$ defined by $((\varphi(x_K))_{K \in \mathcal{M}}, (\varphi(x_{\sigma}))_{\sigma \in \mathcal{E}})$.

3. The finite volume scheme and its convergence analysis

The finite volume method is based on the discretization of the balance equation associated to equation (2) on cell K . It requires the definition of consistent numerical fluxes $(F_{K,\sigma}^{\mathcal{D}})_{K \in \mathcal{M}, \sigma \in \mathcal{E}_K}$ on the edges of the cells, meant to approximate the diffusion fluxes $-\Lambda \nabla u \cdot \mathbf{n}_K$, where \mathbf{n}_K is the unit outward normal to ∂K .

Let \mathcal{F} be a family of finite volume discretizations; for $\mathcal{D} = (\mathcal{M}, \mathcal{E}, \mathcal{P}) \in \mathcal{F}$, $K \in \mathcal{M}$ and $\sigma \in \mathcal{E}$, we denote by $F_{K,\sigma}^{\mathcal{D}}$ a linear mapping from $X_{\mathcal{D}}$ to $\mathbb{R}^{\mathcal{E}}$. The family $((F_{K,\sigma}^{\mathcal{D}})_{\substack{K \in \mathcal{M} \\ \sigma \in \mathcal{E}}})_{\mathcal{D} \in \mathcal{F}}$ is said to be a consistent

Finite volumes for anisotropic diffusion problems on general grids

family of fluxes if for any function $\varphi \in C^2(\mathbb{R}^d, \mathbb{R})$,

$$\lim_{h_{\mathcal{D}} \rightarrow 0} \max_{\substack{K \in \mathcal{M} \\ \sigma \in \mathcal{E}_K}} \frac{1}{m_{\sigma}} \left| F_{K,\sigma}^{\mathcal{D}}(P_{\mathcal{D}}(\varphi)) + \int_{\sigma} \Lambda_K \nabla \varphi \cdot \mathbf{n}_{K,\sigma} d\gamma \right| = 0, \quad (6)$$

where $\Lambda_K = \frac{1}{m_K} \int_K \Lambda dx$. In order to get some estimates on the approximate solutions, we need a coercivity property: the family of numerical fluxes $((F_{K,\sigma}^{\mathcal{D}})_{\substack{K \in \mathcal{M} \\ \sigma \in \mathcal{E}}})_{\mathcal{D} \in \mathcal{F}}$ is said to be coercive if there exists $\alpha > 0$ such that, for any $\mathcal{D} = (\mathcal{M}, \mathcal{E}, \mathcal{P}) \in \mathcal{F}$ and for any $u \in X_{\mathcal{D},0}$,

$$\sum_{K \in \mathcal{M}} \sum_{\sigma \in \mathcal{E}_K} (u_K - u_{\sigma}) F_{K,\sigma}^{\mathcal{D}}(u) \geq \alpha \|u\|_{1,\mathcal{D}}^2. \quad (7)$$

Finally the family of numerical fluxes $((F_{K,\sigma}^{\mathcal{D}})_{\substack{K \in \mathcal{M} \\ \sigma \in \mathcal{E}}})_{\mathcal{D} \in \mathcal{F}}$ is said to be symmetric if for any $\mathcal{D} = (\mathcal{M}, \mathcal{E}, \mathcal{P}) \in \mathcal{F}$, the bilinear form defined by

$$\langle u, v \rangle_{\mathcal{D}} = \sum_{K \in \mathcal{M}} \sum_{\sigma \in \mathcal{E}} F_{K,\sigma}^{\mathcal{D}}(u)(v_K - v_{\sigma}), \quad \forall (u, v) \in X_{\mathcal{D},0}^2,$$

is such that

$$\langle u, v \rangle_{\mathcal{D}} = \langle v, u \rangle_{\mathcal{D}}, \quad \forall (u, v) \in X_{\mathcal{D},0}^2.$$

The finite volume scheme may then be written by approximating the integration of (2) in each control volume, and requiring that the scheme be conservative:

$$\text{Find } u^{\mathcal{D}} = ((u_K^{\mathcal{D}})_{K \in \mathcal{M}}, (u_{\sigma}^{\mathcal{D}})_{\sigma \in \mathcal{E}}) \in X_{\mathcal{D},0}; \quad (8)$$

$$\sum_{\sigma \in \mathcal{E}_K} F_{K,\sigma}^{\mathcal{D}}(u^{\mathcal{D}}) = \int_K f(x) dx, \quad \forall K \in \mathcal{M}; \quad (9)$$

$$F_{K,\sigma}^{\mathcal{D}}(u^{\mathcal{D}}) + F_{L,\sigma}^{\mathcal{D}}(u^{\mathcal{D}}) = 0, \quad \forall \sigma \in \mathcal{E}_{\text{int}}, \mathcal{M}_{\sigma} = \{K, L\}. \quad (10)$$

or, in equivalent form:

$$\text{Find } u^{\mathcal{D}} = ((u_K^{\mathcal{D}})_{K \in \mathcal{M}}, (u_{\sigma}^{\mathcal{D}})_{\sigma \in \mathcal{E}}) \in X_{\mathcal{D},0} \text{ s.t. } \langle u^{\mathcal{D}}, v \rangle_{\mathcal{D}} = \int_{\Omega} f(x) P_{\mathcal{M}} v(x) dx, \quad \forall v \in X_{\mathcal{D},0}. \quad (11)$$

THEOREM 3.1. – *Under assumptions (4), let u be the unique solution to (5). Consider a regular family of admissible meshes \mathcal{F} , along with a family of consistent, coercive and symmetric fluxes $((F_{K,\sigma}^{\mathcal{D}})_{\substack{K \in \mathcal{M} \\ \sigma \in \mathcal{E}}})_{\mathcal{D} \in \mathcal{F}}$.*

Then, for all $\mathcal{D} \in \mathcal{F}$, there exists a unique $u^{\mathcal{D}} \in X_{\mathcal{D},0}$ solution to (10) or (12), and $P_{\mathcal{M}} u^{\mathcal{D}}$ converges to u , solution of (5) in $L^q(\Omega)$, for all $q \in [1, +\infty)$ if $d = 2$ and all $q \in [1, 2d/(d-2))$ if $d > 2$, as $h_{\mathcal{D}} \rightarrow 0$. Moreover, $\nabla_{\mathcal{D}} u^{\mathcal{D}} \in H_{\mathcal{M}}(\Omega)^d$, defined by $m_K(\nabla_{\mathcal{D}} u^{\mathcal{D}})_K = \sum_{\sigma \in \mathcal{E}_K} m_{\sigma}(u_{\sigma} - u_K) \mathbf{n}_{K,\sigma}$ for all $K \in \mathcal{M}$, converges to ∇u in $L^2(\Omega)^d$.

Sketch of proof Taking $v = u^{\mathcal{D}}$ in (12), we get the following *a priori* estimate on $u^{\mathcal{D}}$:

$$\alpha \|u^{\mathcal{D}}\|_{1,\mathcal{D}}^2 \leq \|f\|_{L^2(\Omega)} \|u^{\mathcal{D}}\|_{L^2(\Omega)}.$$

The discrete Sobolev inequality [1] holds thanks to the above definition of $\theta_{\mathcal{D}}$, that is, there exists $C > 0$ depending only on q, Ω and θ such that: $\|P_{\mathcal{M}} u^{\mathcal{D}}\|_{L^q(\Omega)} \leq C \|P_{\mathcal{M}} u^{\mathcal{D}}\|_{1,\mathcal{M}}$. Therefore, thanks to the fact that $\|P_{\mathcal{M}} u^{\mathcal{D}}\|_{1,\mathcal{M}} \leq \|u^{\mathcal{D}}\|_{1,\mathcal{D}}$, we obtain that: $\|P_{\mathcal{M}} u^{\mathcal{D}}\|_{1,\mathcal{M}} \leq \|u^{\mathcal{D}}\|_{1,\mathcal{D}} \leq \frac{C}{\alpha} \|f\|_{L^2(\Omega)}$, which yields the existence and uniqueness of $u^{\mathcal{D}}$. Then, prolonging by 0 the function $P_{\mathcal{M}} u^{\mathcal{D}}$ outside of Ω , we get the estimate

$$\|P_{\mathcal{M}} u^{\mathcal{D}}(\cdot + \xi) - P_{\mathcal{M}} u^{\mathcal{D}}\|_{L^1(\mathbb{R}^d)} \leq |\xi| (d m(\Omega))^{1/2} \|u^{\mathcal{D}}\|_{1,\mathcal{D}}, \quad \forall \xi \in \mathbb{R}^d.$$

We can therefore apply the Fréchet–Kolmogorov theorem, which is a compactness criterion in $L^1(\mathbb{R}^d)$. Again using the discrete Sobolev inequality, we get that, up to a subsequence, $P_{\mathcal{M}}u^{\mathcal{D}}$ converges, for all $q \in [1, +\infty)$ if $d = 2$ and all $q \in [1, 2d/(d-2))$ if $d > 2$, in $L^q(\mathbb{R}^d)$ to some function \tilde{u} , with $\tilde{u}(x) = 0$ for a.e. $x \in \mathbb{R}^d \setminus \Omega$. Furthermore, in the spirit of lemma 2 of [4], we can show that $\nabla_{\mathcal{D}}u^{\mathcal{D}}$ converges to $\nabla\tilde{u}$ weakly in $L^2(\mathbb{R}^d)^d$. Therefore $\tilde{u} \in H_0^1(\Omega)$. To complete the proof of the theorem, we pass to the limit $h_{\mathcal{D}} \rightarrow 0$ on the weak form of the scheme: for $\varphi \in C_c^\infty(\Omega)$, we take $v = P_{\mathcal{D}}(\varphi)$ in (12). Using the symmetry and the consistency (7) of the fluxes $F_{K,\sigma}^{\mathcal{D}}(\varphi)$, we obtain that \tilde{u} verifies (5) with $v = \varphi$. Therefore, by uniqueness, $\tilde{u} = u$ and the whole sequence converges. The strong convergence of $\nabla_{\mathcal{D}}u^{\mathcal{D}}$ to ∇u is obtained, using (8), the convergence of $\langle u^{\mathcal{D}}, u^{\mathcal{D}} \rangle_{\mathcal{D}}$ to $\int_{\Omega} \nabla u \cdot \Lambda \nabla u dx$ and following the principles of the proof of lemma 2.6 in [5].

4. An example of consistent, coercive and symmetric family of fluxes

Let us first note that the case of the classical four point finite volume schemes on triangles (also based on a consistent coercive and symmetric family of fluxes, see [6]) is included in the framework presented here. However, for general meshes or anisotropic diffusion operators, the construction of an approximation to the normal flux is more strenuous [2, 3, 7]; it is often performed by the reconstruction of a discrete gradient, either in the edges of the cell, or in the cell itself. We propose the following numerical fluxes, defined for $u \in X_{\mathcal{D}}$ by

$$F_{K,\sigma}(u) = -m_{\sigma} \left(\nabla_{\mathcal{D}}u_K \cdot \Lambda_K \mathbf{n}_{K,\sigma} + \alpha_K \left(\frac{R_{K,\sigma}(u)}{d_{K,\sigma}} - \sum_{\sigma' \in \mathcal{E}_K} m_{\sigma'} \frac{R_{K,\sigma'}(u)}{d_{K,\sigma'}} (x_{\sigma'} - x_K) \cdot \frac{\mathbf{n}_{K,\sigma}}{m_K} \right) \right)$$

where Λ_K is the mean value of the matrix $\Lambda(x)$ for $x \in K$, $\nabla_{\mathcal{D}}u_K$ is defined in Theorem 3.1, $R_{K,\sigma}(u) = u_{\sigma} - u_K - \nabla_{\mathcal{D}}u_K \cdot (x_{\sigma} - x_K)$, and $(\alpha_K)_{K \in \mathcal{M}}$ is any family of strictly positive real numbers, bounded by above and below. We thus get a consistent, coercive and symmetric family of fluxes, in the above stated sense. In fact, in the same spirit as in the scheme derived in [5] for meshes satisfying an orthogonality condition, the above expression for $F_{K,\sigma}(u)$ is deduced from the variational form of the scheme, which is based on the following inner product:

$$\langle u, v \rangle_{\mathcal{D}} = \sum_{K \in \mathcal{M}} \left[m_K \nabla_{\mathcal{D}}u_K \cdot \Lambda_K \nabla_{\mathcal{D}}v_K + \alpha_K \sum_{\sigma \in \mathcal{E}_K} \frac{m_{\sigma}}{d_{K,\sigma}} R_{K,\sigma}(u) R_{K,\sigma}(v) \right], \quad \forall u, v \in X_{\mathcal{D},0}.$$
